TITLE INDEX

α-Rays of 2 cm. Range, Origin of, J. Schintlmeister, 477

Aberdeen University, Prof. W. Garstang appointed to take charge temporarily of the Natural History Department, 772

Ability and Knowledge: the Standpoint of the London School, F. C. Thomas (*Review*), 423

Absorption Coefficients of the Bands 4774, 5770 and 6290A. of Oxygen, L. Herman and Mme. Renée Herman-Montagne, 216

Abyss: Nearing the, the Lesson of Ethiopia, Lord Davies (*Review*), 1072

Académie des Inscriptions et Belles Lettres, Paris, Sir Robert Mond elected an associate foreign member of the, 1002

Acetone, Photo-decomposition of, Mechanism of the, Dr. R. Spence and Dr. W. Wild, 206

Acetylcholine: Actions of, on the Brain, Henderson and Wilson, 129; Containing Heavy Hydrogen, Prof. H. Erlenmeyer, H. Lobeck and Prof. K. Fromherz, 1063

Acetylene, Development of the Chemistry of, Dr. O. Nicodemus, 475

Acid Silver Nitrate Reaction, Value of the, as a Test of Ascorbic Acid, A. Giroud and C. P. Leblond, 247

Actinomyces Group, Pathogenic Aerobic Organisms of the, Miss D. Erikson, 170

Adenylic Acid in Vitamin B_1 Deficiency, Role of, Dr. T. W. Birch and Dr. L. W. Mapson, 27

Administration: A Definite Profession, E. S. Byng, 653; and Technology in Industry, 653

Administrative and Technical Worker, Place and Function of the, in the New Forms of Economic Structure, S. W. Smith, 653

Adrenalectomized Rats, High Potassium Diet and the Survival of, Dr. R. A. Cleghorn and G. A. McVicar, 124

Aerobacter aerogenes, Fermentation of some Diabasic C_4 Acids by, H. A. Barker, 217

Aeronautics, Skin-Friction in, The Part Played by, Dr. F. W. Lanchester, 1022

Aeroplane: Height Record: G. Détré, 324; New, Squadron Leader F. R. D. Swain, 580; Materials, Research in, New Laboratory for, 610; The Book of the, Capt. J. L. Pritchard. Third edition (*Review*), 1037

Africa: Native Policy in, W. G. A. Ormsby-Gore, 107; Dr. L. P. Mair (*Review*), 947; Artificial Lakes in, Proposal for, 717

African: Honey Bees, Prof. T. D. A. Cockerell, 249; Surveys, Co-ordination of, Brig. MacLeod, 255; Colonies, Mapping of our, Brig. H. S. L. Winterbotham, 452; Problems, W. G. A. Ormsby-Gore, 680

Africans, Ten, Edited by Margery Perham (*Review*), 947

Agricultural: Botany, National Institute of, Annual Meeting, 158; Research: Farmer's Guide to, 199; Institutes in Great Britain, Report for 1933–34, 239; and other Experiments, Mathematical Treatment of the Results of, Prof. M. J. Van Uven (*Review*), 347; and Horticultural Pests, Leaflet on, 755; Research: Empire Co-operation in, 777; Experiments, The Half-Drill Strip System, "Student", 971; Prof. R. A. Fisher, 1101; Situation, World, in, 1934–35, 1091

Agriculture: The New, and World Peace (*Review*), 58; Mathematics and, Dr. J. Wishart (*Review*), 347; and Fisheries, Ministry of, Leaflets of the, 583

Air: Conditioning in Living Rooms, 409; Ministry Research Station, Bawdsey Manor, R. A. Watson Watt appointed superintendent of the, 460; Natural Convection in, Effect of Pressure upon, O. A. Saunders, 855; -Conditioned Flats, 877; and Vapour Locks in Fuel Systems, M. A. A. Allfrey, 937; Raid Precautions in Factories and Business Premises, 1089

Airmen's Reactions, Study of, 1061

Akustik, Einführung in die angewandte, Dr. H. J. von Braunmühl und W. Weber (*Review*), 310

Albite-Fayalite, System, N. L. Bowen and J. F. Schairer, 378

Alcoholism and Psychiatry, Prof. D. K. Henderson (Norman Kerr memorial lecture), 715

Alcohols: various, High-frequency Absorption of, R. Zouckermann and R. Freymann, 217; at 3μ, Intermolecular Forces and O—H Absorption Bands in, Prof. J. Errera and Dr. P. Mollet, 882; Primary, Method for the Rapid Diagnosis and Approximate Estimation of the, S. Sabetay, 1112

Aldehydes and Ketones, Photodecomposition of, Dr. R. G. W. Norrish and C. H. Bamford, 1016

Aleutian Islands' Skull of Abnormal Size, Dr. A. Hrdlička, 613

Algæ: Periodicity in, M. S. Randhawa, 251; a Fungal Parasite of, D. J. Scourfield, 1105

Alkaline: Metals in Natural Waters, Search for the, R. Bossuet, 339; Glasses, Action of Hydrogen on, at a High Temperature, M. A. Foex, 943; Rocks of Chilwa, Southern Nyasaland, Dr. F. Dixey, 1020

All-About: The Story of a Black Community on Argyle Station, Kimberley, Mary and Elizabeth Durack (*Review*), 1074

Allene Compound, Resolution of an, P. M. Raitland and W. H. Mills, 514

Allium Schœnoprasum L., Different Results in Reciprocal Crosses between Diploid and Triploid, A. Levan, 508

Allotments could be made an Amenity Asset to the Community, How, Lady Allen of Hurtwood, 927

Alloys: Metals and, Structure of, Dr. W. Hume-Rothery (*Review*), 7; Order-Disorder Transition in, C. Sykes and F. W. Jones, 936; Nickel-Iron, Magnetic Properties of the, 940

Almandine Garnets in some Devonian Igneous Rocks of Victoria, A. B. Edwards, 91

Alpine Studies (*Review*), 8

Alps, The Structure of the, Prof. L. W. Collet. Second edition (*Review*), 8

Alternating-Current Machines, A. F. Puchstein and Prof. T. C. Lloyd (*Review*), 666

Altitude Record, New World, G. Détré, 324; Squadron Leader F. R. D. Swain, 580

Aluminium: Luminescence of Barrier Anodes of, K. Guminski, 180; and its Alloys, Some Properties of, G. Gauthier; Marquis de Fleury and Dr. H. Portier; Prof. A. von Zeerleder and Dr. R. Irmann, 691; N. D. Pullen; Prof. Portevin and Dr. P. Bastien, 692; Luminescence of Barrier Anodes of, K. Guminski, 897 in Animal Tissues, P. Meunier, 943

America, Central, Cultural Origins in, Dr. W. D. Strong, 1045

American: Association, Dr. F. G. Novy presented with the 250,000th microscope produced by Bausch & Lomb, 67; Mercantile Marine, Records of the, 110; University, Problems of an, President of California University, 136; Medical Association, award of medals to Dr. C. B. Huggins, Dr. S. W. J. Noonan, Dr. B. H. Blockson, G. C. Supple, S. Ansbacher and Dr. A. L. Barach, 160; Amaryllis Year Book. Vol. 2, 239; Steam-boats, Use of Coal in [1836], 299; Physical Education honorary award made to Dr. Edgar and Dr. Edwin Fauver, 361; Early Tertiary Mammals, 427; Ceramic Society, Prof. R. Riecke nominated an honorary member of the, 460; Life, Place of Higher Learning in, Dr. R. Pound, 518; Research Grants, 542; Ophthalmological Society, Lucien Howe medal of the, award of the, to Sir John Parsons, 927; Society of Mechanical Engineers, award of the A.S.M.E. medal to Dr. E. Bausch and the Holley medal to H. Ford, 963; Inventions, Twelve Notable, 1088

Amides and Anilides, Infra-red Absorption and Raman Spectra of, and the Structure of these Compounds, Mme. Marie Freymann and René Freymann, 90

Ammonia: Ordinary and Heavy, Refractive Indexes of, O. E. Frivold, Prof. O. Hassel and S. Rustad, 330; and Carbon Dioxide, Reaction between, T. Yoshida, 695

Ammonium Mandelate in Urinary Infections, 649

Analysis, Elementary, Lessons in, Dr. G. S. Mahajani. Second edition (*Review*), 784

Anarchy or Peace, Lord Davies, 321

Anatoxins purified by Precipitation with Trichloracetic Acid, Flocculating and Immunizing Properties of, G. Ramon, A. Boivin and R. Richou, 774

Ancient: Monuments, Illustrated Regional Guides to, W. G. A. Ormsby-Gore. Vol. 3: East Anglia and Midlands, 875; Buildings in Scotland and England, 1073

Aneurin and Thiochrome, The Structure of, F. Bergel and A. R. Todd, 76; 119

Angiospermic Carpel, Dr. I. V. Newman, 209

Animal: Fibres, Reactivity of the Sulphur Linkage in, Dr. J. B. Speakman, 43; Products, 170; Life in the Forth Area (*Review*), 703, Kingdom, Parade of the, Prof. R. Hegner, assisted by Jane Z Hegner (*Review*), 780

Animals, Wild, at Large (*Review*), 780

Animaux sauvages de l'Afrique, La vie des, Dr. É. Gromier (*Review*), 780

Anophelines in Captivity, Swarming of the Males of certain European, Dr. L. W. Hackett and M. Bates, 506

Antarctica,: My Flight Across, L. Ellsworth, 238; Discoveries in, 1047

Anthropology: Social, Methods in, Prof. E. Westermarck (Huxley memorial lecture), 808; As It Is, A. M. Hocart (*Review*), 904

Antibodies, Ultracentrifugal and Electrophoretic Studies on, Prof. M. Heidelberger, K. O. Pedersen and A. Tiselius, 165

Anti-Noise Regulations of Philadelphia, 398

Antiscorbutic Activity of a Derivative of Gluconic Acid, Prof. B. A. Lawrow, Prof. W. M. Rodionow, E. M. Bomdas and N. S. Jarussowa, 40

Antithyrotropic Activity, Rowlands and Parkes, 82

Anti-Vivisection Finance, Sir Leonard Rogers, 71

Apothecaries, Society of, The Herbarizing Dinner of the [1836], 137

Apple Stock, Northern Spy, Miss J. Hearman, 936

Apples: Spray Covering on, K. Groves and J. Marshall, 294; Immunity of, to Woolly Aphis, 513; Gas Storage of, Kidd and West, 1062

Apseudes talpa, Feeding Mechanism of, and the Evolution of the Peracaridan Feeding Mechanisms, R. Dennell, 896

Aquarist and Pond-Keeper, March–April, 360

Arachnida, Regeneration in, T. H. Savory, 550; G. H. Locket, 885

Arc Discharge, Cathode of an, A Second Sheath near the, N. Warmoltz, 36

Archæological: Discoveries at Předmost, Dr. J. Matiegka 104; Excavations in Britain, 320, 321

Archæology in Western Colombia, Dr. H. Wassén, 333

Arctic: Marine Prosobranchs, Breeding of, 213; Shore Fauna of the, H. Madsen, 806

Argentine Ant in the United States, M. R. Smith, 647

Argon, Neon and Helium, J. T. Randall, 191

Armaments: Science and, 261; Economic and Military, The Common Menace of, Prof. W. E. Rappard (Richard Cobden lecture), 394; and the Scientific Worker, 987

Arminghall Timber Monument, Dr. J. G. D. Clark, 470

Arms, Private Manufacture and Trading in, Royal Commission on the, Report, 987

Armstrong College, Report of Standing Committee for Research, 375

Ascarids, Glycogen Content of, I. Smorodincev and K. Bebeshin, 561

Ascension, Island of, Geology of the [1836], 137

Ascorbic: Acid: Value of the Acid Silver Nitrate Reaction as a Test of, A. Giroud and C. P. Leblond, 247; in Plant Tissues, The State of, G. L. Mack, 505; (Vitamin C), Estimation of, by Titration, Dr. I. Gál; H. Cheftel and Marie-Louise Pigeaud, 799; Biosynthesis of, Prof. B. C. Guha and B. Ghosh, 844; in Plant Tissues, State of, Dr. L. F. Levy, 933; Acids, Synthetic and 'Natural', Divergent Physiological Effects of, L. Havas and I. Gál, 586

Asia: Northern, Molluscs of, A. Mozley, 517; Minor, Geology of [1836], 773

Asianic Deities in the Paganism of Ancient Georgia, Prof. M. Tseretelli, 512

Asien, Geologie von, Prof. K. Leuchs. Band 1, Teil 1 (*Review*), 228

Assyrian Chemistry and Geology, A Dictionary of, Dr. R. Campbell Thompson (*Review*), 1035

Astronomy: Present-day, Some Problems of, Sir James Jeans, 538; For All (*Review*), 821; Highlights of, Prof. W. Bartky (*Review*), 821; International Co-operation in (*Review*), 902

Astrophysics: A Programme for (*Review*), 628; Theoretical, Atomic Theory and the Analysis of Stellar Atmospheres and Envelopes, Prof. S. Rosseland (*Review*), 628

Astrophysik, Handbuch der, Herausgegeben von G. Eberhard, A. Kohlschütter, H. Ludendorff. Band 7 (*Review*), 1079

Athens, The British School of Archæology at, 659

Athos, the Monks of, Prof. R. M. Dawkins (*Review*), 228

Atlas, A New 'Oxford' (*Review*), 307

Atmospheric: Vorticity, K. Nakata, 41; Oscillations, C. L. Pekeris, 642; Pollution, Research on, 963

Atmospherics: Lightning and, P. F. Fyson, 278; P. R. Coursey, 509; at Madras, Wave Forms of, C. V. Rajam, 1064

Atom, The, Prof. E. N da C. Andrade. New edition (*Review*), 348

Atomic: Physics: Progress in, Conference at Copenhagen, 42; Hydrogen and the Disappearance of Hydrogen in Discharge Tubes, R. Delaplace, 179; Spectra: Introduction to, Prof. H. E. White (*Review*), 525; The Theory of, Prof. E. U. Condon and Dr. G. H. Shortley (*Review*), 525; Nuclei: Properties and Constitution of, Prof. N. Bohr, 695; Splitting of, under the Influence of Neutrons on Rare Earths, G. Hevesy, 774

Atoms, Complex, Theory of, Prof. D. R. Hartree, Dr. B. Swirles and Dr. H. S. W. Massey, 1080

Attis: Sacrifice to, A Study of Sex and Civilization, Dr. W. A. Brend (*Review*), 952

Aucuba japonica (Thunb.), A Bacillus Isolated from Diseased Plants of, Dr. G. Trapp, 40

Aurora Borealis of October 11, 1836, 655

Auroral: Afterglow, Effect of Oxygen on the, Prof. J. Kaplan, 35; Arcs, Directions of Homogeneous, R. A. Hamilton, 1059; Phenomena and the Behaviour of the Ionosphere during a Total Solar Eclipse, Prof. L. Vegard, 974

Auroras, Red and Sunlit, and the State of the Upper Atmosphere, Prof. L. Vegard, 930

Australia: Official Year Book of the Commonwealth of, No. 28, 1935, E. T. McPhee (*Review*), 9; Geological Survey of, 21; Scientific and Industrial Research, Council for, Ninth Annual Report, 21; Radio Research in, 214; Scientific and Industrial Research in, 278; Weed Problems in, 434; Control of the Prickly-Pear in, A. P. Dodd; Dr. A. D. Imms, 911; South, Soil Drift in the Arid Pastoral Areas of, F. N. Ratcliffe, 1039; North, C. P. Conigrave (*Review*), 1074; The Impact of Civilization in (*Review*), 1074

Australian: Soils, Microbiology of, H. L. Jensen, 208; Plants, Cyanogenetic Glucosides in, H. Finnemore and Joyce M. Cooper (4), 260; Aborigines, Administrative Classification of, Paterson, 715

Australopithecus, The Dentition of, Dr. R. Broom, 719

Autopolyploidy, Dr. A. Muntzing, 252

Avon Biological Research, Third Annual Report on, 614

Axolotl, Larval Transplantation in, Kolodziejski, 371

β-Myrcene, Study of, G. Dupont and V. Desreux, 855
Babylonian Astronomy, Late, Numerical methods in, Prof. O. Neugebauer, 849
Bacterial: Epidemiology and Nutrition, 474; Nutrition, B. C. J. G. Knight, 474; Flora of Sea and Land Breezes, Qualitative Study of the, C. E. ZoBell and Helen M. Mathews, 1070
Bacteriophage Substance, The Feulgen Reaction of the, Dr. M. Schlesinger, 508
Bacterium prodigiosum, Independence of the Production of Proteases and the Development of the Cell in, W. Moycho, 179
Ba-ga-Malete of Ramoutsa, History of the, V. Ellenbeyer, 180
Baganda Institutions, Sir Apolo Kagwa, translated by E. B. Kalibala. Edited by May Mandelbaum (Edel), 540
Bakelized Bearings, 171
Ballooning, Progress of [1836], 299
Bantu, Aptitudes of the, F. M. C. Stokes, 1059
Bay Islands, Spanish Honduras, Birds of, J. Bond, 725
Beams and Lattice Girders, Application of Influence Lines to the Stress Analysis of, R. McCrae. Part 2, 852
Beams Ultracentrifuge, The, W. C. Fahie and R. H. J. Brown, 207
Beauty, In Search of (*Review*), 1035
Bedfordshire Vermin Payments, J. S. Elliot, 614
Bedouin, Physical Characters of the, Dr. W. M. Shanklin, 251
Bee-Keeping in India, C. C. Ghosh. Third edition, 1061
Behavior: Motivation of, the Fundamental Determinants of Human and Animal Activity, Prof P. T. Young (*Review*), 666
Beilby Layer on Non-Metals, The, Prof. G. I. Finch, 1010
Beit fellowships for scientific research, award of, 177
Belfast, Queen's University, Dr. W. H. McCrea appointed professor of mathematics, 136
Belgium, Formation of a Ministry of Health in, 282
Bell, Sir Charles, leaves London [1836], 257
Ben Bullen Plutonic Complex, N.S.W., G. A. Joplin, 259
Bennett, Edward Turner, death of [1836], 299
Benzene: Structure of, Prof. C. K. Ingold and others, 472; and its Derivatives, Absorption Spectra of, in the Near Infra-Red (6000–9500 A.), P. Barchewitz, 985
Benzoin and Thymol, Condensation of, O. Dischendorfer and A. Verdino (2), 49
Berkeley: George, a Study of his Life and Philosophy, Prof. J. Wild (*Review*), 818
Berkeley's Idealism, The Phases of, Prof. G. Dawes Hicks (*Review*), 818
Bermuda, Underwaters of, Seasonal Changes in the, Prof. W. Garstang, 60
Berzelius awarded the Copley medal [1836], 941
Bessel Functions, Some Formulæ for the Associated Legendre Functions of the Second kind, with corresponding Formulæ for the, Prof. T. M. McRobert, 896
Beta-Rays, Emission of, from substances Bombarded with Neutrons, S. Kikuchi, H. Aoki and K. Husimi, 841
Bibliography, Co-operation in, 716
Bierhefe als Heil-, Nahr- und Futtermittel, Die, Dr. J. Schulein (*Review*), 665
Binary Mixtures, Viscosity of, Dr. A. J. A. Van der Wyk, 845
Biochemical Progress (*Review*), 741
Biochemie des Menschen und der Tiere, Handbuch der, Herausgegeben von Prof. C. Oppenheimer. Zweite Auflage. Ergänzungswerk. Band 3 (*Review*), 309
Biochemistry: Review of, A. L. Bacharach (*Review*), 309; and Medicine, Training of Chemists for work in, Sir Henry Dale, 557; Annual Review of. Edited by J. M. Luck. Vol. 5 (*Review*), 741
Biography, The Technique of (*Review*), 740
Biological: Chemists, Society of, at Bangalore, Prof. E. Abderhalden nominated an honorary member of the, 160; Books in 1935, Prices of, J. R. Miner, 196; Society of Vienna, Prof. W. Heubner elected an honorary member of the, 797
Biology: Unapplied, A Text-Book of, C. Dobell (*Review*), 523; of Water-Supply, Exhibit of, at the British Museum (Natural History), 964
Biot at the Collége de France [1836], 90
Bird: -Ringing and Bird Migration, Lord Mansfield, 89; -Song, Records of, 610; Flight, G. C. Aymar (*Review*), 1037; Migration · a Short Account, Dr. A. L. Thomson; Prof. W Rowan (*Review*), 1078
Birds: British, How to Know, Dr. N. H. Joy (*Review*), 424; of the Firth of Clyde, The, J. M. McWilliam (*Review*), 424; of the Green Belt and the Country Around London, R. M. Lockley (*Review*), 424, Migrations of, Dr. A. L. Thomson, 554; Australian, Food of, late A. M. Lea and J. T. Gray, 592; Useful, Advisory Leaflets on, 614; Diseases of, J. Reis, P. Nobrega and A. S. Reis, 847; of Agricultural Importance, Advisory Leaflets on, 1092
Birmingham University: gifts by Sir William Waters Butler and Sir Charles Hyde, Bt., 156; C. G. Parsons awarded a Walter Myers travelling studentship; Dr. M. Stacey appointed lecturer and F. Smith assistant lecturer in chemistry; Dr. A. Lamont assistant lecturer in geology; and J. W. Drinkwater lecturer in mechanical engineering, 215; and City, Annual Report for 1935–36 of the Joint Board for Mental Disease, 541
Bisulphite Compounds, Method of extracting Aldehydes and Ketones from their, A. Barrot, 855
Bitumen and Petroleum in Antiquity, R. J. Forbes (*Review*), 632
Black-Body Radiation, The Cepheid Variables and, A. E. H. Bleksley, 286
Blatt-Minen Mittel und Nord-Europas, Die, Prof. M. Hering. Lief 2: Brunella-Filipendula (*Review*), 704
Blood: Circulation of the, Prof. R. J. S. McDowall, 454; Group Investigation, Prof. R. R. Gates, 470; Circulation of the, The Control of the, Prof. R. J. S. McDowall, 488, Pigments (*Review*), 662; An Effect of X-Radiation on the, Dr. H. L. Brose and E. B. Jones, 687; Volume, Total, A New Microcolorimetric Apparatus and a Method for Determination of, Dr. J. C. Somogyi, 763
Blow-fly: Larvæ, Bacterial Flora of, Dr. N. Balzam, 889; A New, Attacking Sheep in Western Scotland, Dr. J. MacLeod, 467
Boat Construction in Ancient Scandinavia and Oceania, J. Hornell, 765
Bohadsch 1761, Proposed Suspension of Rules of Nomenclature in the Case of, C. W. Stiles, 206
Boiling Points, Normal, A Simplified Procedure for Determining, by the Comparative Method, Dr. M. Wojciechowski, 1096
Boric Anhydride, Reduction of, by Manganese, H. Forestier and Mlle. Myriam Graff, 1026
Borneo, West, Fishes from, Dr. J. D. F. Hardenberg, 806
Boron: the *K*-Radiation of, J. Serpe, 179; and Lithium, Ranges of Particles Emitted in the Disintegration of, by Slow Neutrons, J. Rotblat, 202; Crystallized, the K-Radiation of, A. Hautot, 258; and Cadmium, Neutron Absorption of, at Low Temperatures, V. Fomin, F. G. Houtermans, A. I. Leipunsky, L. B. Rusinow and L. W. Schubnikow, 505
Botanical: Progress, Twenty-five Years of, 373; Society of London [1836], 376; Society of Japan, Prof. R. Kolkwitz elected an honorary member of the, 1093
Botany: for Children, Lady Elphinstone (*Review*), 784
Botany Bay, Change of Sea-level at, C. A. Sussmilch, 897
Bounty: The Heritage of the, The Story of Pitcairn through Six Generations, Dr. H. L. Shapiro (*Review*), 382
Bracken as a Weed, 706
Brain: Respiration, Effect of Dichlor-Diethyl-Sulphone on, Prof. R. A. Peters, 327; Trust' in American Politics, 559; Size in Man and the Great Apes, Dr. F. Weidenreich, 689
Braithwaite's Steam Floating Fire Engine [1836], 655

(Branchiopoda), Body Orientation of the Lower Crustacea, J. H. Lochhead, 232

Bristol and Gloucester District, F. B. A. Welch and R. Crookall, 389

Britain: The Land of, Part 78: Berkshire, J. Stephenson, with an Historical Section by W. G. East (*Review*), 227

British: Museum (Natural History), Recent Acquisitions, 21; Empire: Economic Products of the, 21; Cancer Campaign, Acceptance by Viscount Hailsham of the Chairmanship, 24; Medical Association, Annual Meeting of the, 71; Honduras, Forests and Flora of, P. C. Standley and Prof. S. J. Record; A. L. Howard (*Review*), 145; Guiana, Insect Life of Temporary Rain Swamps in, F. A. Squire, 151; School of Archæology at Athens, 159; Museum (Natural History), Recent Acquisitions at the, 196; Bird, New, J. J. Harrison; W. P. Lowe, 251; Association: Blackpool Meeting of the, 274; at Bristol [1836], 300; School of Archæology at Athens, 323; Association at Bristol [1836], 337; 376; Stem- and Leaf-Fungi (Cœlomycetes), W. B. Grove. Vol. 1 (*Review*), 384; Association and Social Science, Incorporation of the British Science Guild, 431; Science Guild, Incorporation in the British Association, 431; Association: A Scientific Survey of Blackpool and District, Edited by A. Grime (*Review*), 485; Meetings; Sir Edward B. Poulton elected president for 1937, 497, Commonwealth Scientific Conference, 539; School of Archæology: at Rome, C. A. R. Radford appointed director, 614; at Athens, The, 659; Chemical Manufacturers, Association of, Activities of the, 680; Dr. E. F. Armstrong re-elected president, 681; Museum (Natural History): Recent Acquisitions, 754, impending retirement of Dr. W. T. Calman, 792; M. A. C. Hinton appointed keeper of zoology, 793; Surveying in South American Seas [1836], 854; Telegraph Services, Developments in, L. H. Harris, E. H. Jolley and F. D. Morrell, 893; Museum (Natural History), Acquisitions at the, 964; Association, appointment of officers for 1937, 1004; Film Institute, Third Annual Report, 1067; Honduras, Forestry in, 1049; Institute of Radiology: Annual Congress and Exhibition, 1024; Launderers' Research Association, 1004; Mosquito Control Institute, Work of the, 1046

Brittle Stars from Puerto Rico, H. Clark, 371

Broadcasting: Electrical Interference with, 181; 255; International Relations Promoted by, 678

Bromacetates, Action of, on Various Alkaloids, L. Espil and G. Mandillon, 258

Bromine: III, Structure of, Dr. K. R. Rao, 168; Radioactive Isotopes of, Dr. C. H. Johnson and F. T. Hamblin, 504

Bronze Age Burials in Scotland, L. Mann, 236

Brooklyn Botanic Garden, Twenty-fifth anniversary, 373

Bruce, Dr. W. S., memorial prize, award of the, to J. W. S. Marr, 67

Brussels and Antwerp Railway [1836], 732

Buchanan, Original Laterite of, Dr. C. S. Fox, 649

Buckland's "Bridgewater Treatise" on Geology [1836], 598

Building: Research Station, New Heating Laboratory at the, 156; A. F. Dufton, 335; Research Board, Work of the, 878

Burns, Modern Treatment of, 555

Business: Mental Activity and Management, W. R. Dunlop, 23; Careers, Preparation for, E. I. Lewis, 732;

Butter, Firmness of, Influence of Chemical Composition on the, J. Lyons, 338

Cadmium: Metallic Zinc and, Asymmetry in, Prof. K. Herrmann; Dr. G. W. Brindley, 290; Boron and, Neutron Absorption of, at Low Temperatures, V. Fomin, F. G. Houtermans, A. I. Leipunsky, L. B. Rusinow and L. W. Schubnikow, 505; with Tertiary Arsines, Co-ordination Compounds of, G. J. Burrows and A. Lench, 813; Ferrite, Decomposition of, H. Forrestier and F. Redslob, 1112

Cairina moschata and *Anas platyrhyncha platyrhyncha*, Genetical and Cytological Studies of the Intergeneric Hybrid of, Prof. F. A. E. Crew and P. C. Koller, 178

Calciferol and Vitamin D_3, Chemistry of, A. L. Bacharach, 387

Californian Shrimps of Commerce, H. R. Israel, 208

Cambridge: Oxford and, Co-operation between, 678; Philosophical Society, election of officers, 838; University: G. C. Evans appointed Frank Smart student in botany and Dr. L. E. R. Picken Balfour student; grant from the Balfour Fund made to J. D. Robertson, 46; T. R. B. Sanders appointed lecturer in engineering; W. W. Brigden elected Marmaduke Shield scholar in anatomy; award of Frank Smart prizes to G. Metcalfe and E. T. Burtt; Dr. D. W. Babbage elected an official fellow of Magdalene College, 89; A. L. Hodgkin elected Michael Foster student; O. L. Zangwill and J. W. S. Pringle elected Martin Thackeray students at King's College, 215; Prof. R. S. Hutton elected a professorial fellow of Clare College; C. O. Hutton awarded an external studentship at Emmanuel College, 299; Dr. J. H. Hutton appointed lecturer in the faculty of archæology and anthropology, 394; award of Frank Edward Elmore studentships to A. C. E. Cole, G. D. Hadley, L. C Martin and B. McArdale; Dr. H G. Booker appointed assistant lecturer in mathematics and Mrs. J. V. Robinson assistant lecturer in economics and politics; resignation of Dr. T. S. Hele, H. W. Hall, W. A. Fell, R. S. Handley, Dr. M. Born and T. C. Nicholas, 518; H. Hunter appointed director of the Plant Breeding Institute; appointments to the Solar Physics Observatory of W. Moss, J. C. Dobbie and E. G. Williams, 693; D. H. Valentine appointed curator of the Botanical Museum and Herbarium; Dr. N. Feather, M. H. L. Pryce, A. L. Hodgkin and T. T. Paterson elected fellows of Trinity College, 731; grants from the Balfour Fund made to W. Graham-Smith and H. E. Hinton; Sir Albert Seward elected an honorary fellow of Downing College, 772; Prof. T. Von Kármán appointed Rouse Ball lecturer for 1936–37; E. N. Willmer elected an official fellow of Clare College; J. F. Brock appointed assistant director of research in medicine; J. S. Baxter appointed demonstrator in anatomy; Dr. V. J. Chapman elected an unofficial Drosier fellow of Gonville and Caius College, 853; M. Krook elected an Isaac Newton student and E. N. Rowland an additional Isaac Newton student; Prof. W. V. D. Hodge elected a non-stipendiary fellow of Pembroke College, 895; The I.C.I., Ltd. and Work on Molecular Rays; K. P. Harrison appointed Benn W. Levy student, 940; Miss H. G. Wanklyn appointed lecturer in geography, and Dr. S. R. Nockolds demonstrator in mineralogy and petrology, 1025; recommended that Dr. U. R. Evans continue assistant director of research in metallurgy and that G. E. Briggs be appointed reader in plant physiology, 1067; award of the Adam Smith prize to D. G. Champernowne, 1110

Camphor, Solutions of, in Organic Solvents, Circular Dichroism of, G. Bruhat and P. Guénard, 896

Canada: National Research Council, Eighteenth Annual Report, 236; Petroleum Fuels in, 336; Mining in, 359; Forestry Research in, 396; Mineral Wealth of, 878

Canadian: Water Power Developments during 1935, Dr. B. Cunningham, 10; Work on Dermatophyte Fungi, 176; Eastern Arctic, Flora of the, N. Polunin, 331; Reindeer Herd, 542

Cancer: Research: Grants for, 119; awards for, made to Prof. E. L. Kennaway and Prof. J. W. Cook, 579; Congress, International, Second, 727; Treatment of, with an Enzyme Solution ('Ensol'), Dr. H. C. Connell, 888; Research in Great Britain, 999; Research Fund, Imperial, Thirty-fourth Annual Report, 1935–36, 1085

Canyons, Submarine, Underlying Causes of, F. P. Shepard, 775

Caoutchouc, Crystallized, Elementary Lattice of, K. H. Meyer and W. Lotmar, 259

Cape Town University, Gen. Smuts elected Chancellor, 584

Carbohydrate: Breakdown in Early Embryonic Development, Mechanism of, Dr. J. Needham, W. W. Nowinski, R. P. Cook and K. C. Dixon, 462; Metabolism: Dr. H. Weil-Malherbe, 551; G. K. McGowan and Prof. R. A. Peters, 552; Sodium and Water Metabolism in Relation to Disturbances of, after Adrenalectomy, Prof. F. Verzár and L. Laszt, 844; Oxidation, Mechanism of, Dr. F. Dickens, 1057

Carbohydrates, Intermediate Metabolism of, Dr. H. A. Krebs, 288

Carbon: Dendrites, Formation of, K. D. Luke, Dr. W. M. Madgin and Dr. H. L. Riley, 161; Dioxide, Solid, Dr. I. J. Faulkner, 191; Dendrites, Formation of, Dr. H. Thiele, 688; Dioxide, Carbonyl Sulphide and Carbon Disulphide, Resonance Structures of, Dr. A. Clow and J. M. C. Thompson, 802; Disulphide, Carbon Dioxide, Carbonyl Sulphide and, Resonance Structures of, Dr. A. Clow and J. M. C. Thompson, 802; Dioxide, Prof. E. L. Quinn and C. L. Jones (*Review*), 993

Carbonyl Sulphide, Carbon Dioxide and Carbon Disulphide, Resonance Structures of, Dr. A. Clow and J. M. C. Thompson, 802

Caries in Children's Teeth, Influence of Diet on, 956

Carnations, Anther Smut of, Dr. H. L. White, 848

Carnegie Institution of Washington, Report for Year ending October 31, 1935, 542

Carolina 'Bays', Prof. D. Johnson, 471

Cartilage: Metabolism of: E. G. L. Bywaters, 30; Dr. F. Dickens and Dr. H. Weil-Malherbe, 125; E. G. L. Bywaters, 288

Cascade Range, Oregon, Diorites of the, A. F. Buddington and E. Callaghan, 513

Cass, Sir John, Technical Institute, Opening of the Thirty-fifth Session, 693

γ-Cassiopeia, Spectrum of, Remarkable Variation in the, D. Chalonge, 560

Casuarina, A Fossil, from near Bacchus Marsh, Victoria, R. T. Patton, 91

Catalysts, Preparation of, New Method for the, L. Faucounau, 561

Cathay, The Quest for, Brig.-Gen. Sir Percy Sykes (*Review*), 1036

Caucasian Studies, 499

Cells, Living, Death of, Increase of Diamagnetic Susceptibility on the, Prof. E. Bauer and A. Raskin, 801

Cellulose, Molecular Structure of, G. F. Davidson, 175

Celtic Studies, J. M. de Navarro (John Rhys memorial lecture), 1089

Central American Studies: The Copan Project, Dr. A. V. Kidder, 1089

Centrifuging in Rotating Hollow Cylinders, Dr. M. Schlesinger, 549; Dr. E. A. Hauser and C. E. Reed, 975

Cepheid Variables, The, and Black-Body Radiation, A. E. H. Bleksley, 286

Cercospora Leaf-Spot of Tobacco, A. V. Hill, 209

Cereals of Ancient Egypt and Mesopotamia, Prof. J. Percival, 270

Ceylon, Marine Work in, A. H. Malpas, 877

Chadwick gold medal and prize, presentation of the, to E. A. Drew, 756

Chamberlain memorial at Birmingham University, 156

Champollion: Monument to [1836], 257; and Hieroglyphics, 278

Charaka Club, The Proceedings of the, Vol. 8 (*Review*), 663

Cheeses, Ripening of, E. Parisi and G. de Vito, 340

Chemical: Engineering Congress of the World Power Conference, 44; Warfare, The Medical Profession and, 155; Industry, Society of, annual meeting at Liverpool, 172; Reactions, Catalysis of, in organisms, Dr. J. H. Quastel, 607; Dr. P. Eggleton, 608

Chemischer und chemischtechnischer Vortrage, Sammlung F. B. Ahrens. Herausgegeben von Prof. R. Pummerer-Erlangen. Neue Folge, Heft 33: Die Azoxyverbindungen, Dr. E. Muller (*Review*), 864

Chemist: The, as World Citizen, W. A. S. Calder, 173; Training the, for Service to the Community, Prof. J. C. Philip, 449

Chemistry: Organic: Developments in (*Review*), 224; Physical Aspects of, Dr. W. A. Waters (*Review*), 224; Inorganic: A Text-Book of, edited by Dr. J. Newton Friend. Vol. II, Part 3 (*Review*), 268; and Theoretical, A Comprehensive Treatise on, Dr. J. W. Mellor. Vol. 15 (*Review*), 310; General, an Elementary Survey; Emphasizing Industrial Applications of Fundamental Principles, Prof. H. G. Deming. Fourth edition (*Review*), 424; and the Modern State, Prof. J. C. Philip, 492; Physical, for Colleges, Prof. E. B. Millard. Fourth edition (*Review*), 528; and the Community, 557; Organic, Benign Gifts of, C. J. T. Cronshaw, 557; Industrial, Developments in (*Review*), 568; Inorganic: Prof. N. Bjerrum. Translated by R. P. Bell (*Review*), 626; The Field of (*Review*), 626; Organic: A Text-Book of, late Dr. J. Schmidt. English edition by Dr. H. G. Rule. Third edition (*Review*), 633; Recent Advances in, Prof. A. W. Stewart. Vol. 2, with the addition of Part 2, by Dr. H. G. Graham (*Review*), 633; and Food Science, Dr. L. Harris, and others, 744; Physical, A Text-Book of, Sylvanus J. Smith (*Review*), 864; and Geology, Early (*Review*), 1035; American, Annual Survey of, Vol. 10, 1935. Edited by C. J. West (*Review*), 1079

Chemotherapy, An Institute of, 961

Chiasma Formation, Induced, in Somatic Cells by a Carcinogenic Hydrocarbon, E. Marie Hearne, 291

Child Neurology Research, 878

Chimie industrielle, Cours de, Prof. G. Dupont. Tome 1 et 2 (*Review*), 568

Chimpanzee: Sexual and Reproductive Cycles of, R. M. Yerkes and J. H. Elder, 91; Metabolism, F. G. Benedict and J. M. Bruhn, 415; Reproduction in the, J. H. Elder and R. M. Yerkes, 725

China: Seas, Oceanography and Meteorology of, 83; Tattooing in, Prof. C. H. Liu, 370; The Birth of, A Survey of the Formative Period of Chinese Civilization, Dr. H. G. Creel (*Review*), 565; The Early Cultures of (*Review*), 565

Chinese: Materia Medica (*Review*), 484; Medicinal Plants from the Pen Ts'ao Kang Mu, A. D. 1596, Dr. B. E. Read. Third edition (*Review*), 484; Glass, Early, from Pre-Han to T'ang Times, Prof. C. G. Seligman, Dr. P. D. Ritchie and H. C. Beck, 721

Chironomid Fauna of the Mosses of the River Liffey, C. F. Humphries and W. E. Frost, 300

Chloroform, Heavy, $CDCl_3$, R. Truchet, 179

Chlorophyll: Monomolecular Layers of, W. Sjoerdsma, 405; Reversible Oxidation and Reduction of, Dr. E. Rabinowitch and Dr. J. Weiss, 1098

Chloroplast, The Plant, K. Kiyohara, 848

p-Chlortoluene, Chlorination of, H. Wahl, 258

Choline: of Sperm, Origin of the, E. Kahane and Mlle. Jeanne Lévy, 258; Esterase, Absolute Activity of, L. H. Easson and E. Stedman, 767

Chordate Head, The, de Lange, 471

Christiansen Filters, G. Ahier, 48

Chromium Carbides, Formation of, R. Testut, 1026

Chromosome Size, Genotypic Control of, P. T. Thomas, 402

Chromosomes: *in situ*, Demonstration of, Projection Method for, Dr. C. D. Darlington and H. C. Osterstock, 79; The External Forces Acting on, J. L. Fyfe; Dr. C. D. Darlington, 366

Citrin, Chemical Nature of, V. Bruckner and Prof. A. Szent-Gyorgyi, 1057

Civilization, Modern, The Strain of, Lord Horder, 529

Civil List Pensions, 119

Clarke's Magneto-Electric Machine [1836], 655

Clinical Research (*Review*), 619

Clocks showing Mean and Sidereal Time Simultaneously, F. Hope-Jones, 931

Cloud Chamber Observations of Cosmic Rays, C. D. Anderson and S. H. Neddermeyer, 555
Clouds, Vertical Motion in, Studied by Cinematograph Pictures, W. Schmidt, 218
Clyde Estuary, Geology of the [1836], 854
Coal: Low Temperature Carbonization of, 130; Hydrogenation of, A French Process, F. Vollette, 473; Measures, Correlation of the, Prof. A. E. Trueman, 705; Gas: Gum in, H. Hollings, 876; Research, 876; Oxidation of, H. Lefebvre and R. Faivre, 943; its Constituents and Uses, Prof. W. A. Bone and Dr. G. W. Himus. With a Supplementary Chapter upon Fuel Economy and Heat Transmission in Industrial Furnaces by Dr. R. J. Sarjant (*Review*), 991; King, Sir R. A. S. Redmayne (*Review*), 991
Cœlenterates, New Work on, Prof. O. Carlgren, 371
Cœlomycetes, Some British, E. W. Mason (*Review*), 384
Coffee: Biography of (*Review*), 702; The Saga of, The Biography of an Economic Product, H. E. Jacob. Translated by Eden and Cedar Paul (*Review*), 702
Coiled-Coil Lamp, Development of the, W. Geiss, 130
Cokes, Domestic, A. Marsh and others, 964
Coleoptera, Morphology of, W. H. Anderson; R. E. Blackwelder, 1019
Coleopterologica, Bibliographia (*Review*), 310
Colloid: Osmotic Pressure of the Body Fluids of Freshwater Animals, Dr. P. Meyer, 287; Subtrate in Photosynthesis, Dr. M. Copisarow, 509
Colloids and the Biological Effect of Radiation, F. Ellinger, 1014
Colonial: Policy and Scientific Research, W. G. A. Ormsby-Gore, 3; Office Appointments: 72; 324; 502; 682; 879; 1008; Territories, The Demand for, and Equality of Economic Opportunity, 754
Colorado, Early Man in, 459

Columbia Encyclopedia, The, C. F. Ansley, Editor-in-Chief (*Review*), 901
Comet, 1936, Observations of the, P. Rossier, 985
Comets: Observations on, 240; 1818 I, 1873 VII, 1928 III, Identity of, Dr. A. C. D. Crommelin, 1105
Community, Science and the, 417
Complex Compounds in Solution, Application of Certain Physical Methods to the Search for, R. Tréhin, 943
Compounds of the Type R_xMX_4, Optical Properties and Crystal Structure of Some, D. P. Mellor and F. M. Quodling, 477
Compression Ignition Engines (*Review*), 527
Compton Effect: Scattering and Recoil in the, Correlation between, Dr. J. C. Jacobsen, 25; Prof. E. L. Hill, 209
Conchology, Library of, Presented by Sohtsu G. King to the Science Society of China Library, Shanghai, 110
Cone-Sheets, Ring-Dykes and Caldron-Subsidences, Dynamics of the Formation of, E. M. Anderson, 48
Conjuring, Indian, Lt.-Col. R. H. Elliot, 425
Conquest: Reaction to, Effects of Contact with Europeans on the Rondo of South Africa, Dr. Monica Hunter (*Review*), 947
Constants and Numerical Data, Annual Tables of, 681
Construction, Science of, Pioneer in the, S. B. Hamilton, 1089
Continental Motions, Dr. R. Gunn, 848
Cook Islanders, Physical Characters of the, Dr. H. L. Shapiro and Dr. P. H. Buck (Te Rangi Hiroa), 725
Copepods: German, Dr. O. Pesta, 293; from the Great Barrier Reef, G. P. Farran, 1062
Copper: and Silver, Divalent, Magnetic Study of the Mixed Crystals of, L. Capatos and N. Perakis, 48; Sulphate Pentadeuterate, Dissociation Pressure of, Dr. F. Schacherl and O. Běhounek, 406; Surface of, Formed by Solidification *in vacuo*, S. Dobinski and Dr. C. F. Elam, 685; Nickel and, Radioactive Isotopes of, Dr. C. B. Madsen, 722
Coral: Reef Ecology at Low Isles, 173; Reefs, Ecological Surveys of, Dr. S. M. Manton, 173; -Infesting Crabs, Family Hapalocarcinidæ, Dr. Chia-Jui-Shen, 935
Corona during the Total Solar Eclipse of June 19, The, Prof. M. Navashin, 73

CORRESPONDENCE

Acetone, Photo-Decomposition of, Mechanism of the, Dr. R. Spence and Dr. W. Wild, 206
Acid Silver Nitrate Reaction as a Test of Ascorbic Acid, Value of the, A. Giroud and C. P. Leblond, 247
Adenylic Acid in Vitamin B, Deficiency, Role of, Dr. T. W. Birch and Dr. L. W. Mapson, 27
Adrenalectomized Rats, High Potassium Diet and the Survival of, Dr. R. A. Cleghorn and G. A. McVicar, 124
African Honey Bees, Prof. T. D. A. Cockerell, 249
Agricultural Experiments, The Half-Drill Strip System, "Student", 971; Prof. R. A. Fisher, 1101
Alcohols at 3μ, Intermolecular Forces and O–H Absorption Bands in, Prof. J. Errera and Dr. P. Mollet, 882
Aldehydes and Ketones, Photodecomposition of, Dr. R. G. W. Norrish and C. H. Bamford, 1016
Allium Schœnoprasum L., Different Results in Reciprocal Crosses between Diploid and Triploid, A. Levan, 508
Ammonia, Ordinary and Heavy, Refractive Indexes of, O. E. Frivold, Prof. O. Hassel and S. Rustad, 330
Aneurin and Thiochrome, The Structure of, F. Bergel and A. R. Todd, 76, 119
Anophelines in Captivity, Certain European, Swarming of the Males of, Dr. L. W. Hackett and M. Bates, 506
Antibodies, Ultracentrifugal and Electrophoretic Studies on, Prof. M. Heidelberger, K. O. Pedersen and A. Tiselius, 165
Arachnida: Regeneration in: T. H. Savory, 550; G. H. Locket, 885
Arc Discharge, A Second Sheath near the Cathode of an, N. Warmoltz, 36
Ascorbic: Acid: Value of the Acid Silver Nitrate Reaction as a Test of, A Giroud and C. P. Leblond, 247; in Plant Tissues, The State of, G. L. Mack, 505; Synthetic and 'Natural', Divergent Physiological Effects of, L. Havas and I. Gál, 586; Acid: (Vitamin C), Estimation of, by Titration, Dr. I. Gál; H. Cheftel and Marie-Louise Pigeaud, 799; Biosynthesis of, Prof. B. C. Guha and B. Ghosh, 844; in Plant Tissues, State of, Dr. L. F. Levy, 933
Atmospheric Oscillations, C. L. Pekeris, 642
Atmospherics, Lightning and, P. R. Coursey, 509
Auroral: Afterglow, Effect of Oxygen on the, Prof. J. Kaplan, 35; Phenomena and the Behaviour of the Ionosphere during a Total Solar Eclipse, Prof. L. Vegard, 974; Arcs, Homogeneous, Directions of, R. A. Hamilton, 1059
Auroras, Red and Sunlit, and the State of the Upper Atmosphere, Prof. L. Vegard, 930
Australopithecus, The Dentition of, Dr. R. Broom, 719
Bacteriophage Substance, The Feulgen Reaction of the, Dr. M. Schlesinger, 508
Bantu, Aptitudes of the, F. M. C. Stokes, 1059
Beams Ultracentrifuge, The, W. C. Fahie and R. H. J. Brown, 207
Beilby Layer on Non-Metals, The, Prof. G. I. Finch, 1010
Beta-Rays, Emission of, from Substances Bombarded with Neutrons, S. Kikuchi, H. Aoki and K. Husimi, 841
Binary Mixtures, Viscosity of, Dr. A. J. A. Van der Wyk, 845
Black-Body Radiation, The Cepheid Variables and, A. E. H. Bleksley, 286
Blood: An Effect of X-Radiation on the, Dr. H. L. Brose and E. B. Jones, 687; Volume, Total, A New Microcolorimetric Apparatus and a Method for Determination of, Dr. J. C. Somogyi, 763
Blowfly, A New, Attacking Sheep in Western Scotland, Dr. J. MacLeod, 467
Bohadsch 1761, Proposed Suspension of Rules of Nomenclature in the Case of, C. W. Stiles, 206
Boiling Points, Normal, A Simplified Procedure for Determining, by the Comparative Method, Dr. M. Wojciechowski, 1096
Boron: and Lithium, Ranges of Particles Emitted in the Disintegration of, by Slow Neutrons, J. Rotblat, 202; and Cadmium, Neutron Absorption of, at Low Temperatures, V. Fomin, F. G. Houtermans, A. I. Leipunsky, L. B. Rusinow and L. W. Schubnikow, 505

Brain Respiration, Effect of Dichlor-Diethyl-Sulphone on, Prof. R. A. Peters, 327
Bromine: III, Structure of, Dr. K. R. Rao, 168; Radioactive Isotopes of, Dr. C. H. Johnson and F. T. Hamblin, 504
Cadmium: Metallic Zinc and, Asymmetry in, Prof. K. Herrmann; Dr. G. W. Brindley, 290; Boron and, Neutron Absorption of, at Low Temperatures, V. Fomin, F. G. Houtermans, A. I. Leipunsky, L. B. Rusinow and L. W. Schubnikow, 505
Canadian Eastern Arctic, Flora of the, N. Polunin, 331
Carbohydrate: Breakdown in Early Embryonic Development, Mechanism of, Dr. J. Needham, W. W. Nowinski, R. P. Cook and K. C. Dixon, 462; Metabolism, Dr. H. Weil-Malherbe, 551; G. K. McGowan and Prof. R. A. Peters, 552; Disturbances, after Adrenalectomy, Sodium and Water Metabolism in Relation to, Prof. F. Verzár and L. Laszt, 844; Oxidation, Mechanism of, Dr. F. Dickens, 1057
Carbohydrates, Intermediate Metabolism of, Dr. H. A. Krebs, 28
Carbon: Dendrites: Formation of, K. D. Luke, Dr. W. M. Madgin and Dr. H. L. Riley, 161; Formation of, Dr. H. Thiele, 688; Disulphide, Carbon Dioxide, Carbonyl Sulphide and, Resonance Structures of, Dr. A. Clow and J. M. C. Thompson, 802; Dioxide, Carbonyl Sulphide and Carbon Disulphide, Resonance Structures of, Dr. A. Clow and J. M. C. Thompson, 802
Carbonyl Sulphide, Carbon Dioxide, Carbon Disulphide and, Resonance Structures of, Dr. A. Clow and J. M. C. Thompson, 802
Cartilage: Metabolism of: E. G. L. Bywaters, 30; Dr. F. Dickens and Dr. H. Weil-Malherbe, 125; E. G. L. Bywaters, 288
Cells, Living, Increase of Diamagnetic Susceptibility on the Death of, Prof. E. Bauer and A. Raskin, 801
Centrifuging in Rotating Hollow Cylinders, Dr. M. Schlesinger, 549; Dr. E. A. Hauser and C. E. Reed, 975
Cepheid Variables, The, and Black-Body Radiation, A. E. H. Bleksley, 286
Chiasma Formation, Induced, in Somatic Cells by a Carcinogenic Hydrocarbon, E. Marie Hearne, 291
Chinese Glass, Early, from Pre-Han to T'ang Times, Prof. C. G. Seligman, Dr. P. D. Ritchie and H. C. Beck, 721
Chlorophyll: Monomolecular Layers of, W. Sjoerdsma, 405; Reversible Oxidation and Reduction of, Dr. E. Rabinowitch and Dr. J. Weiss, 1098
Chromosome Size, Genotypic Control of, P. T. Thomas, 402
Chromosomes: *in situ*, Projection Method for Demonstration of, Dr. C. D. Darlington and H. C. Osterstock, 79; The External Forces acting on, J. L. Fyfe; Dr. C. D. Darlington, 366
Citrin, Chemical Nature of, V. Bruckner and Prof. A. Szent-Gyorgyi, 1057
Clocks showing Mean and Sidereal Time Simultaneously, F. Hope-Jones, 931
Colloid: Osmotic Pressure on the Body Fluids of Freshwater Animals, Dr. P. Meyer, 287; Substrate in Photosynthesis, Dr. M. Copisarow, 509
Colloids and the Biological Effect of Radiation, F. Ellinger, 1014
Compton Effect, Scattering and Recoil in the, Correlation between, Dr. J. C. Jacobsen, 25

Cyclohexane Rings, Multiplanar, Non-existence of, Dr. R. D. Desai and Prof. R. F. Hunter, 548
'Cyclol' Molecules, Energy of Formation of, Dr. D. M. Wrinch, 241; C. F. Frank, 242
Cyclones, Ascent of Air in, Dr. A. H. R. Goldie, 166
Cyclopropane, Raman Spectrum of, R. Ananthakrishnan, 123
Dead Sea, Life in the, Dr. B. Wilkansky, 467
Deuterium: Water, Equilibria in Salt Systems with, F. T. Miles, R. W. Shearman and Prof. A. W. C. Menzies, 121; Solid Hydrogen and, at 4·2° K., Density and Compressibility of, Miss H. D. Megaw and Prof. F. Simon, 244; Thermal Conductivity of, C. T. Archer, 286; Use of, as an Indicator in Stereochemical Investigations, Prof. H. Erlenmeyer, H. Schenkel and A. Epprecht, 547; Helium, Hydrogen and, Thermal Properties of, A. Bijl, 723; Metallic Hydrogen and, Expansion Pressures of, A. R. Ubbelohde, 845
Deuteroethylenes, Symmetrical, Provisional Computation of the Plane Vibration Frequencies of, Prof. C. Manneback and A. Verleysen, 367
Devernalization of Winter Rye by High Temperature, Prof. F. G. Gregory and O. N. Purvis, 1013
Diamagnetism of Mixtures of Organic Liquids, Prof. J. F. Spencer and Dr. V. C. G. Trew, 974
Diamond, Surface Markings on a, Dr. W. H. George, 616
Diastase in Rabbit Saliva, I. M. Thomas, 1015
Diatomic Sulphur, Selenium and Tellurium Vapours, Dissociation Energy of, P. Goldfinger, W. Jeunehomme and B. Rosen, 205
Dichlor-diethyl-sulphone, Effect of, on Brain Respiration, Prof. R. A. Peters, 327
Dilute Traces, Physiological Potency of, Sir Joseph Larmor, 929
Dimethyl Ether, Influence of Nitric Oxide on the Thermal Decomposition of, Gaseous Catalysis, P. F. Gay and Prof. M. W. Travers, 546
Drosophila: Male, A Case of 50 per cent Crossing-over in the, D. Moriwaki, Dr. G. Eloff, 34; *melanogaster*: Immunological Detection of the *Y*-Chromosome in, Dr. S. G. Levit, S. G. Ginsburg, V. S. Kalinin and R. G. Feinberg, 78; Two Unusual Modifications of Eye Colour in, Dr. E. V. Enzmann and C. P. Haskins, 165; Several Spontaneous Chromosome Aberrations in, Dr. S. L. Frolova, 204; Influence of Temperature on Crossing-over in, H. Fairfield Smith, 329; *melanogaster*: During Late Larval Stage, Behaviour of Local, Dr. G. Eloff, 402; A Case of Complete Reversion of a Chromosomal Rearrangement in, Dr. H. Gruneberg, 508
Dyes in the Molecular State, Spectral Absorption and Fluorescence of, Dr. E. E. Jelley, 1009
Ear, Internal, Physical Nature of Certain of the Vibrating Elements of the, C. S. Hallpike, Prof. H. Hartridge and Dr. A. F. Rawdon-Smith, 839
Eel-grass Disease and Parasite on the American Atlantic Coast, Persistence of the, C. E. Renn, 507
Einstein's Theory, a Fundamental Difficulty of, Minimal Lines and Geodesics within Matter, Dr. L. Silberstein, 1012
Electric Discharge, Chemical Reaction in the, Mechanism of, Dr. E. J. B. Willey, 1054

Electrification of a Roof during a Thunderstorm, W. F. Tyler, 724
Electrolytes and a General Phenomenon in Tissue Cells, Prof. H. Grossfeld, 31
Electron Oscillator, A New, Prof. K. Okabe, 685
Electrons, Fast, Passage of, through Matter, H. J. Bhabha and Dr. W. Heitler, 401
Emitters GeCl and GeBr, Ultra-Violet Band Systems of the, L. A. Bashford, Prof. H. V. A. Briscoe and Dr. W. Jevons, 883
Enamel Protein, Dr. P. Pincus, 970
Erosion, Normal, as a Factor in Soil Profile Development, G. Milne, 548
Ethylene Molecule, Vibrations of the, S. Bhagavantam, 1096
Eucalypts, Differentiation of Varieties of, by their Essential Oils, A. R. Penfold and F. Morrison, 1099
Eucalyptus: *Johnstoni*, *Eucalyptus Globulus* and, Chromosome Number of, Prof. A. L. McAulay, F. D Cruickshank and R. G. Brett, 550
Evolution, Atrophy, Burial, Suppression or Total Loss in, Prof. H. A. Harris, 928
Fatty Acids in Organic Mixtures, Estimation of, E. R. Hiscox and J. Harrison, 32
Feathers, Bilateral Gynandromorphism in, P. G. 'Espinasse, 645
Fermentation, Oxidation and, Stereoisomeric Nature of, Dr. G. A. Gause, 245
Feulgen Reaction of the Bacteriophage Substance, The, Dr. M. Schlesinger, 508
Flavins in Normal Human Urine, Determination and Excretion of, A. Emmerie, 164
Flavones, Vitamin Nature of, A. Bentsáth, S. Rusznyák and Prof. A. Szent-Gyorgyi, 798
Flavonols as Vitamins, Vitamin P: S. Rusznyák and Prof. A. Szent-Gyorgyi, 27
Fluorescent Substances, Photo-reduction of, by Ferrous Ions, Dr. J. Weiss, 80
Fossil: Human: Skull from Swanscombe, Kent, Preliminary Note on a New, A. T. Marston, 200; Remains from Kanam and Kanjera, Kenya Colony, Dr. L. S. B. Leakey, 643
Fourier Series in Crystal Analysis: Calculation of Structure Factors and Summation of Noncentrosymmetrical Projections, Dr. J. M. Robertson, 683
Galaxies, The Background of the, Prof. E. A. Milne, 38
Gas Reactions: Kinetics of, An Attempt to Connect Thermal Decomposition and Oxidation Processes, Prof. M. W. Travers, 26
Gaseous: Combustion, Prof. W. T. David, 930; Organic Compounds, Mechanism of Thermal Change in, Prof. M W. Travers, 967
Geiger-Müller Counters, Steady Performance of, Prof. B. Dasannacharya and G. S. Rao, 289
Genetics in the Universities, Dr. E. Ashby, Prof. F. A. E. Crew, Dr. C. D. Darlington, E. B. Ford, Prof. J. B. S. Haldane, Prof. E. J. Salisbury, Dr. W. B. Turrill and C. H. Waddington, 972; Prof. W. Neilson Jones, 1058
Glutathione, Reduced, The Nitroprusside Reaction as a Test for, N. S. R. Maloeuf, 75
Gondwana Affinities of the Angora Flora in the Light of Geological Evidence, The, Prof. B. Sahni, 720
Growth: Substance *B*, Chemistry of, N. Nielsen and V. Hartelius, 203; Hormones and Development of Plants, Prof. N. G. Cholodny, 586
Gulf Stream, An Ecological Aspect of the, Dr. A. C. Redfield, 1013
Hæmoglobin, Ultra-violet Absorption Spectrum of, G. A. Adams, 368
Hardness Tester, A, for Microscopical Objects, Dr. E. M. H. Lips and J. Sack, 328
Hawke's Bay Earthquake of February 2–3, 1931, Focal Depth of the, R. C. Hayes, 126
Heavy Nuclear Particles, Interaction of, D. Iwanenko and A. Sokolow, 246
Helium: Radio-: Dr. T. Bjerge, 400; β-Ray Spectrum of, Dr. T. Bjerge and Dr. K. J. Brostrom, 400; II, Liquid, Optical Experiments on, L. W. Shubnikov and A. K. Kikoin, 641; Hydrogen and Deuterium, Thermal Properties of, A. Bijl, 723; Liquid, Latent Heat of Evaporation of, Dr. J Newton Friend, 1102
Herschel Effect, Dependence of the, upon the Surrounding Gas Medium, Mrs. A. Vnukova, 246
High-Voltage Impulses at Controllable Speed, Transmission of, Dr. L. B. Snoddy, Prof. J. W. Beams, W. T. Ham, jun. and H. Trotter, jun., 167
Histone Insulinate, Hypoglycæmic Action of, A. Biasotti, V. Deulofeu and J. R. Mendive, 1101
Horse Hæmoglobin, Total Dissociation of, Dr. J. Steinhardt, 800
Hydrogen: Halide Gases, Optical Polarization Ellipsoids of the, Dr. C. H. Douglas Clark, 126; Solid, and Deuterium at 4·2° K., Density and Compressibility of, Miss H. D. Megaw and Prof. F. Simon, 244; Halide Gases, Kerr Constants of the, Dr. C. H. Douglas Clark and Dr. E. C. Humphries, 248, Isotopes, Electrolytic Separation of the, Temperature Coefficient of the, H. F. Walton and J. H. Wolfenden, 468; and Deuterium, Helium, Thermal Properties of, A. Bijl, 723; Bond, The, and the Structure of Proteins, Dr. D. M. Wrinch and Dr. D. Jordan Lloyd, 758; Metallic, and Deuterium, Expansion Pressures of, A. R. Ubbelohde, 845
Hymenoptera: Tetraploid? Are, B. R. Speicher, 78; Tetraploidy and, F. Greenshields, 330
Insect: Metabolism, Humidity and, K. Mellanby, 124; Coloration: Prof. H. E. Armstrong, 242; Prof. G. D. Hale Carpenter, 243; and Natural Selection, Prof. E. W. MacBride, 365; Prof. G. D. Hale Carpenter, 686
Inverse Diene Synthesis in the Pure Liquid State, Kinetics of an, B. S. Khambata and A. Wassermann, 368; A. Wassermann, 369
Ion Formation, Negative, A New Process of, Dr. F L. Arnot, 162
Ionosphere: at Allahabad, Collisional Friction Frequency in the, G. R. Toshnival, B. D. Pant and R. R. Bajpai, 37; The Lower Regions of the, Prof. R. C. Colwell, A. W. Friend, N. I. Hall and L. R. Hill, 245; *C* Regions of the, Some Observations on the, Dr. H. Rakshit and J. N. Bhar; Prof. S. K. Mitra, 283
Iron: A Radioactive Isotope of, Prof. E. B. Andersen, 76; and Molybdenum, Distortion of, Dr. E. W. Fell, 760
Isomeric *bis*-Thiocamphors, Synthesis of Two, Sir P. C. Rây, 548
Isotopes and Molecular Asymmetry, Dr. T. Iredale, 292
Isotopic Weights by the Doublet Method, Dr. F. W. Aston, 1094
$K\alpha_{1,2}$-Doublet of Some of the Lighter Elements, Effects of Chemical Combination with Oxygen and Fluorine on the, Dr. N. G. Johnson, 1056
Keilin's Cytochrome *c* and the Respiratory Mechanism of Warburg and Christian, H. Theorell, 687
Keratins, Cross-Linkage Formation in, Dr. H. Phillips, 121; Dr. J. B. Speakman, 327
Kerr Constants of the Hydrogen Halide Gases, Dr. C. H. Douglas Clark and Dr. E. C. Humphries, 248
Ketones, Aldehydes, and, Photodecomposition of, Dr. R. G. W. Norrish and C. H. Bamford, 1016
Kidney Phosphatase, Inhibitory Effect of Phloridzin and Phloretin on, Dr. H. Kalckar, 289
Kikuchi Lines from Etched Copper Crystal, Dr. W. Cochrane, 202
Lactic Dehydrogenase from Heart Muscle, Action of Cozymase as the Specific Co-enzyme of, E. Adler, Prof. H. v. Euler and H. Hellstrom, 968
Lakes, Thermal Stratification in, P. Ullyott and P. Holmes, 971
Lauric Acid, Contact Potentials of Reversible Soluble Films of, R. T. Florence, R. J. Myers and Prof. W. D. Harkins, 405
Light: Scattering of, by Light, A. Akhieser, L. Landau and I. Pomeranchook, 206; Diffraction of, by Ultra-Sonic Waves, F. H. Sanders, 285; Constancy of Wavelength of, G. C. Omer, jun., 587; Diffraction of: by Ultra-Sonic Waves, Sir C. V. Raman and N. S. Nagendra Nath, 616; C. R. Extermann, 843; Neutrino Theory of, Inconsistency of the, V. Fock, 1011
Lightning and Atmospherics, P. R. Coursey, 509
Linkage in Man, Dr. Julia Bell and Prof. J. B S. Haldane, 759

Liquid, Specific Heat of a, at Different Temperatures, Prof. Allan Ferguson and A. H. Cockett, 842
Liquids of High Refractive Index, B. W. Anderson and C. J. Payne, 168
Lithium: Alum, Preparation of, Prof. J. F. Spencer and G. T. Oddie (Sister Mary Cecilia, O.P.), 169; Boron and, Ranges of Particles Emitted in the Disintegration of, by Slow Neutrons, J. Rotblat, 202
Luminous Bacteria, Light-Emitting Process of, Quantum Relationship of the, K. L. van Schouwenburg and Johanna G. Eymers, 245
Madder, Glycosides of, R. Hill and D. Richter, 38
Magdalenian 'Raclette' Industry in the Lower Thames Valley, An Early, J. P. T. Burchell, 79
Magnetron, Parallel-plane Diode, D. M. Tombs, 36
Mammalian Development, Organizers in, C. H. Waddington, 125
Manatee of St. Helena, The, G. C. Kitching, 33
Matter: Minimal Lines and Geodesics within, A Fundamental Difficulty of Einstein's Theory, Dr. L. Silberstein, 1012
Mayfly Nymphs, Oxygen Consumption of, in Relation to Available Oxygen, Prof. H. Munro Fox, C. A. Wingfield and B. G. Simmonds, 1015
Mercury Vapour, Sparking Potential of, Dr. F. Ll. Jones and W. R. Galloway, 973
Metallic: Zinc and Cadmium, Asymmetry in, Prof. K. Herrmann; Dr. G. W. Brindley, 290; Films, Sputtered, A New Kind of Ring Phenomenon in, U. K. Bose, 684
Metals, Order of Affinity of, for Copper, Iron, Cobalt and Nickel, Dr. A. S. Russell, 161
Meteoric Trains, Luminosity of, M. A. R. Khan, 933
Methane, Heavy (CH_3D), Absorption Spectrum of, in the Photographic Infra-Red, Drs. W. H. J. Childs and H. A. Jahn, 285
Mice, Genital Organs of Male, A Protective Action of Progesterone on the, H. Burrows, 164
Microcolorimetric Apparatus, A New, and a Method for Determination of Total Blood Volume, Dr. J. C. Somogyi, 763
Mock Suns Observed at Nanda Devi in Garhwal, N. E. Odell, 764
Molecular: Asymmetry, Isotopes and, Dr. T. Iredale, 292; Nitrogen, Effect of, on Molybdenum at High Temperatures, P. Túry and S. Krausz, 331
Molecules, Vibrational Frequencies of, Dr. H. G. Howell, 290
Molybdenum: at High Temperatures, Effect of Molecular Nitrogen on, P. Túry and S. Krausz, 331; Iron and, Distortion of, Dr. E. W. Fell, 760
Natural Selection: Insect Coloration and, Prof. E. W. MacBride, 365; Prof. G. D. Hale Carpenter, 686; Prof. E. W. MacBride, 884; Prof. G. D. Hale-Carpenter, 1017; Prof. J. B. S. Haldane; E. B. Ford, 1053
Nebulæ, Stars and, Continuous Spectra of Certain Types of, Dr. W. M. Cohn, 127
Neutrino Theory of Light, Inconsistency of the, V. Fock, 1011
Neutron Absorption of Boron and Cadmium at Low Temperatures, V. Fomin, F. G. Houtermans, A. I. Leipunsky, L. B. Rusinow and L. W. Schubnikow, 505
Neutrons: Slow, Influence of Temperature on the 'Groups' of, Dr. A. Arsenjewa-Heil, Dr. O. Heil and C. H. Westcott, 462; Resonance Levels for Absorption, of, J. Rotblat, 545; and Protons, Self-Interaction of Dr. D. Iwanenko and A. Sokolow, 684; Two, Evidence for the Expulsion of, from Copper and Zinc by one Fast Neutron, F. A. Heyn, 723; Scattering of, by Protons, E. T. Booth and Dr. C. Hurst, 1011; in Silver, Selective Absorption of, E. H. S. Burhop, R. D. Hill and A. A. Townsend, 1094; Activation of Silver by, Prof. G. Guében, 1095
Newton's Prism in the British Museum, Prof. Ll. W. Taylor, 585
Nickel and Copper, Radioactive Isotopes of, Dr C. B. Madsen, 722
Nicotine Inhibition of Oxidation and Fermentation, Dr. G. F. Gause, 976
Nitrogen: Losses in Green Plants, Dr. W. H. Pearsall and M. C. Billimoria, 801; Compounds from Legume Nodules, Nature of the Excretion of, Prof. A. I. Virtanen, 880; Fixation with Cow-Dung, Prof. N. R. Dhar and S. K. Mukerji, 1060
Nitroprusside Reaction as a Test for Reduced Glutathione, The, N. S. R. Maloeuf, 75
Noise, Measurements of, B. G. Churcher and A. J. King, 329
Nomenclature, Rules of, Suggested Cases for Suspension of, Dr. C. W. Stiles, 34
Non: -Aqueous Solutions, Surface Properties of, R. Aschaffenburg, 644; -Polar Molecule, Polarizability of a, by Pressure, Indication of a Decrease in the, Prof. A. Michels, C. Michels-Veraart and A. Bijl, 509
North-East Land, Water under the Western Ice Cap in, R. Moss, 803
Nova Lacertæ: 1936, Dr. T. W. Wormell and Dr. J. C. Dobbie, 38; Absence of Cosmic Rays from, Dr. J. Barnóthy and Dr. M. Forró, 544
Nuclear: Levels, The Form of, Dr. R. Preiswerk and Dr. H. von Halban, jun., 163; Reactions Due to Neutrons of 2 m.e.v. Energy, E. T. Booth and C. Hurst, 367
Nucleus $^{127}_{53}I$, The Electric Quadrupole Moment of the Dr. T. Schmidt; Dr. S. Tolansky, 404
Number 137, The Mysterious, Sir Flinders Petrie, 81; C. L. T. Griffith, 332
Orchestration, Adjustable Resonators and, Prof. W. A, Osborne, 1059
Organic Halides in Solution, Unimolecular Elimination of the Significance of the Electrical Conduction, Racemization and Halogen Replacement of, Dr. E. D. Hughes, Prof. C. K. Ingold and A. D. Scott, 120
Organizers in Mammalian Development, C. H. Waddington, 125
Orthophosphoric Acids, Sulphuric and, An X-Ray Study of, J. T. Randall, 842
Osmunda, Spiral Structure of Chromosomes in, Dr. Irene Manton, 1058
Ostrea angulata, Habit and Shell-Shape in the Portuguese Oyster, Prof. J. H. Orton, 466
Oxidation and Fermentation, Stereoisomeric Nature of, Dr. G. A. Gause, 245
Oxide Layer: on a Polished Copper Surface, Dr. S. Dobinski, 31; on a Polished Surface, Dr. L. H. Callendar, 291
Oxycholesterilene, Enolization of, Dr. V. A. Petrow, 645
Oxygen: Content of the Stratosphere, Prof. E. Regener, 544; Rate of Absorption of, by Sodium Sulphite Solution, W. S. E. Stickson, 645; Consumption of Mayfly Nymphs in Relation to Available Oxygen, Prof. H. Munro Fox, C. A. Wingfield and B. G. Simmonds, 1015
Ozone as a Heating Factor in the Atmosphere, R. Penndorf, 247
Palæozoic Seismicity, Dr. A. Lamont, 243
Palladium, Electronic Specific Heat in, G. L. Pickard, 123
Paramecium, Effect of Large Centrifugal Forces on, R. H. J. Brown, 843
Parasites in Ruminants, Migrating, Route of, J. H. Tetley, 802
Particle-Observers, Equivalent, Prof. J. L. Synge, 28
Peking Man, W. C. Pei, 1056
Pentadeuterobenzoic Acid, C_6D_5 COOH, Some Properties of, Prof. H. Erlenmeyer and A. Epprecht, 367
Pepsin, Crystalline, Inactivation of, Dr. J. Steinhardt, 74
Perchloric Acid, Absolute, Raman Effect in, R. Fonteyne, 886
Phase Transitions, The Theory of, Dr. L. Landau, 840
Phenylacetic Acid, Effect of, on the Growth of Tomato Plants, Dr. H. L. Pearse, 363
Phloretin, Phloridzin and, Inhibitory Effect of, on Kidney Phosphatase, Dr. H. Kalckar, 289
Phloridzin and Phloretin, Inhibitory Effect of, on Kidney Phosphatase, Dr. H. Kalckar, 289
Phosphagen in Echinoid Muscle and in Electrical Tissue, E. Baldwin and Dr. Dorothy Moyle Needham, 506

Phosphine, Heavy (PD_3), Infra-Red Absorption Spectrum of, Dr. G. B. B. M. Sutherland and G. K. T. Conn, 641
Phosphites, Phosphorous Acid and the, Constitution of, R. Ananthakrishnan, 803
Phosphogluconic Acid, Fermentation of, F. Lipmann, 588
Phosphorescence, Demonstration of, H. Warren, 974
Phosphorous: Acid and the Phosphites, Constitution of, R. Ananthakrishnan, 803; Phosphorus: Colorimetric Estimation of, Dr. H. L. Brose and E. B. Jones, 644
Photographic Plates, Sensitivity of, in the Region λλ 2500–2100 A., A. Hunter and Dr. R. W. B. Pearse, 37
Photo-Reduction of Fluorescent Substances by Ferrous Ions, Dr. J. Weiss, 80
Photosynthesis, Colloid Substrate in, Dr. M. Copisarow, 509
Physico-Chemical Constants, Determination of, Dr. M. Wojciechowski and Dr. E. R. Smith, 30
Physics, Modern, A Treatment of, Prof. M. N. Saha, 464; Prof. E. N. da C. Andrade, 465
Planetary Nebulæ, Chemical Composition of the, T. L. Page, 503
Plant Tissues, State of Ascorbic Acid in, Dr. L. F. Levy, 933
Plants: Growth Hormones and Development of, Prof. N. G. Cholodny, 586; Green, Nitrogen Losses in, Dr. W. H. Pearsall and M. C. Billimoria, 801
Post-Natal Coat Characters and Prenatal Follicle Density, Relationships between, as Affected by Increase in Fœtal Size, Dr. Nancy Galpin, 585
Potassium: Diet, High, and the Survival of Adrenalectomized Rats, Dr. R. A. Cleghorn and G. A. McVicar, 124; Sodium and, Films in the Schumann Region, Transparency of, Prof. W. H. Watson and D. G. Hurst, 124; in the Extreme Red, Narrow Continuous Band of, T. Okuda, 168; in the Brain in Vitamin B_1 Deficiency, H. W. Kinnersley, 368; Mineral and Biological, Comparison of, in Diet Experiments, Dr. A. Lasnitzki and Dr. M. Lasnitzki, 799
Prenatal Follicle Density, Post-Natal Coat Characters, Relationship between, as Affected by Increase in Fœtal Size, Dr. Nancy Galpin, 585
Progesterone, A Protective Action of, on the Genital Organs of Male Mice, H. Burrows, 164
Protactinium (At. No. 91), The $M_{IV,V}$-Absorption Edges of, Prof. V. Dolejšek and V. Kunzl, 590
Proteins: in Mixtures and Concentrated Solutions, Molecular State of, Dr. K. O. Pedersen, 363; Structure of, The Hydrogen Bond and the, Dr. D. M. Wrinch and Dr. D. Jordan Lloyd, 758
Protons, Neutrons and, Self-Interaction of, Dr. D. Iwanenko and A. Sokolow, 684
Protoplasm, Linear Units within, Evidence for, Dr. H. H. Pfeiffer, 1054
Protozoa, Contractile Vacuoles of, Effects of Hypertonic Media on the, Dr. J. A. Kitching, 287
Quantum Theory, Conservation Laws in, Prof. N. Bohr, 25
Rabbit Saliva, Diastase in, I. M. Thomas, 1015
Radiation: Processes, Conservation of Energy in, Dr. E. J. Williams and E. J. Pickup, 461; Colloids and the Biological Effect of, F. Ellinger, 1014
Radioactive Transformations, Mass Equivalent of the Energy in, Prof. A. J. Dempster, 201
Radio: Propagation, Existence of a Surface Wave in, C. R. Burrows, 284; -Helium: Dr. T. Bjerge, 400; β-Ray Spectrum of, Dr. T. Bjerge and Dr. K. J. Broström, 400; Waves, Simultaneous Transmission and Reception of, H. Antoun and F. Minaw, 761; Fadings and Bright Solar Eruptions, H. W. Newton, 1017
Raman: Spectrum: of Cyclopropane, R. Ananthakrishnan, 123; of Thiophosphoryl Chloride, Prof. V. N. Thatte, 468; Spectra of Substances, Excitation of, with the aid of 'Optical Catalysers', Prof. K. Prosad and D. K. Bhattacharya, 510; Effect in Absolute Perchloric Acid, R. Fonteyne, 886
Reaction Kinetics and the Walden Inversion, W. A. Cowdrey, Dr. E. D. Hughes and Prof. C. K. Ingold, 759
Red Blood Corpuscles of Primitive Mammals, The, Prof. E. A. Briggs, 762
Reference Frames, Intrinsic Uncertainty of, M. S. Bartlett, 401
Resonators, Adjustable, and Orchestration, Prof. W. A. Osborne, 1059
Rice Grain, The Amylase System of, during Ripening and Germination, K. V. Giri and A. Sreenivasan, 406
River Bores, Measurement of, Dr. H. Chatley, 207
'Road Runner' of North America, The, Prof. T. D. A. Cockerell, 166
Rotating Hollow Cylinders, Centrifuging in, Dr. E. A. Hauser and C. E. Reed, 975
Rubidium, Continuous Absorption Band of, in the Presence of Foreign Gases, Ny Tsi-Zé and Ch'en Shang-Yi, 1055
Rules of Nomenclature in the Case of Bohadsch 1761, Proposed Suspension of, Dr. C. W. Stiles, 206
Rye, Winter: Devernalization of, by High Temperature, Prof. F. G. Gregory and O. N. Purvis, 1013; Vernalization of, during Ripening, Prof. F. G. Gregory and O. N. Purvis, 973
Saccharide Chains in Glycogens from Different Sources, Length of, D. J. Bell, 289
Salt Systems, Equilibria in, with Deuterium Water, F. T. Miles, R. W. Shearman and Prof. A. W. C. Menzies, 121
Samarium, Ranges of Particles Emitted by, L. Lewin, 326
Science in Schools, The Teaching of, H. S. Shelton, 127; J. A. Lauwerys, 205
Scientific Workers: and War, Dr. E. Barrow and others, 80; Professional Associations of, Dr. W. A. Wooster, 1017
Scientists and War, Dr. C. N. Acharya, 469
Scyllium canicula, Colour in the Dogfish, H. Waring, 1100
Sea Urchin Eggs, Rates of Cleavage of, in Different Latitudes, Prof. H. Munro Fox, 839
Seismicity, Palæozoic, Dr. A. Lamont, 243
Seismograph Stations, Reliability of, R. C. Hayes, 463; Dr. H. Jeffreys, 464
Sidereal Time, Variation of Cosmic Ray Intensity with, Dr. B. F. J. Schonland, B. Delatizky and J. B. Gaskell, 325
Silica: Fused, The 2·73μ Absorption Band in, Dr. D. G. Drummond, 248; Colloidal, in Natural Waters and the 'Silicomolybdate' Colour Test, Dr. A. R. Tourky and Prof. D. H. Bangham, 587
Silicichloroform, Geometrical Constitution of, Prof. M. de Hemptinne and J. Wouters, 884
'Silicomolybdate' Colour Test, Colloidal Silica in Natural Waters and the, Dr. A. R. Tourky and Prof. D. H. Bangham, 587
Silver: Neutrons in, Selective Absorption of, E. H. S. Burhop, R. D. Hill and A. A. Townsend, 1094; Activation of, by Neutrons, Prof. G. Guében, 1095
$[SO_3]_n$, Prof. H. E. Armstrong, 26
Sodium: and Potassium Films in the Schumann Region, Transparency of, Prof. W. H. Watson and D. G. Hurst, 124; and Water Metabolism in Relation to Disturbances of Carbohydrate Metabolism after Adrenalectomy, Prof. F. Verzár and L. Laszt, 844; Chloride, Ultra-Violet Luminescence of, Prof. M. Schein and M. L. Katz, 883
Soil Profile Development, Normal Erosion as a Factor in, G. Milne, 548
Solar: Eclipse, Total, of June 19, The Corona during the, Prof. M. Navashin, 73; Eruptions, Bright, Radio Fadings and, H. W. Newton, 1017
'Solute', Origin of the Word, Prof. J. R. Partington, 646
Solutes in Plants, Translocation of, Dr. A. C. Léemann, 1099
Sound Vibrations, Some New Phenomena Produced by, Prof. F. L. Hopwood, 1059
Spirogyra, Creeping Movements of, D. R. Chesterman and C. L. Foster, 403
Stars and Nebulæ, Continuous Spectra of Certain Types of, Dr. W. M. Cohn, 127
Stearin from Chilled Olive Oil, Inhibited Deposition of, Dr. W. Clayton, S. Back, R. I. Johnson and J. F. Morse, 801

Stellar Atmospheres, Dissociation Energy of Carbon Monoxide and the Abundance of Elements in, M. Nicolet, 1097
Sterckfontein Ape, The, Dr. E. Schwarz, 969
Stereochemical Investigations, Use of Deuterium as an Indicator in, Prof. H. Erlenmeyer, H. Schenkel and A. Epprecht, 547
Stick: Insect, The Common, Sister Carmela Hayes, 886; Insects, Feeding Habits of, S. T E. Dark, 1058
Stratosphere, Oxygen Content of the, Prof. E. Regener, 544
Streptococcus apis, Relation of So-called, to Certain Lactic Acid Streptococci, Dr. J. G. Davis and Dr. H. L. A. Tarr, 763
Structure-Factor Graphs for Crystal Analysis, Prof. W. L. Bragg, 362
Sugars, Different, from the Intestine of Rat and Pigeon, Relative Velocities of the Absorption of, Dr. H. G. K. Westenbrink, 203
Sulphuric and Orthophosphoric Acids, An X-Ray Study of, J. T. Randall, 842
Supraconductivity: Destruction of, by Electric Current and Magnetic Field, L. Shubnikov, 545; Destruction of, by an Electric Current, Transition Curve for the, L. W. Shubnikov and N. E. Alexejevski, 804
Supra-Conductors, Time Effects in, K. Mendelssohn and R. B. Pontius, 29
Surface Forces, Range of Action of, Dr. B. Derjaguin, 330; Dr. J. M. Macaulay, 587
Syndrome produced by Diverse Nocuous Agents, A, Prof. H. Selye, 32
Tetranitromethane, Constitution of, Prof. R. Robinson, 975
Tetraploidy and Hymenoptera, F. Greenshields, 330
Thermal Neutrons in Silver at Low Temperatures, Absorption of, V. Fomin, F. G. Houtermans, I. W. Kurtshatov, A. I. Leipunski, L. Shubnikov and G. Shtshepkin, 326
Thiochrome. Aneurin and, The Structure of, F. Bergel and A. R. Todd, 76, 119; Synthesis of, F. Bergel and A. R. Todd, 406
Thiophosphoryl Chloride, Raman Spectrum of, Prof. V. N. Thatte, 468
Thorium, Uranium and, Atomic Masses of, Prof. A. J. Dempster, 120
Threads, Rotating, Stability of, H. W. Hall, 932
Thyroglobulin, Association and Dissociation Reactions of, Dr. H. P. Lundgren, 122
Tissue Cells, Electrolytes and a General Phenomenon in, Prof. H. Grossfeld, 31
Tissues, Analysis of, for Metallic Content, H. Ramage, 762
Tomato Plants, Growth of, Effect of Phenylacetic Acid on the, Dr. H. L. Pearse, 363
Total Solar Eclipse, Auroral Phenomena and the Behaviour of the Ionosphere during a, Prof. L. Vegard, 974
Triterpene Group, A Novel Interrelationship in the, J. H. Beynon, Prof I. M. Heilbron and Dr. F. S. Spring, 1017
Ultra-Sonic Waves, Diffraction of Light by, F. H. Sanders, 285
Unimolecular Elimination and the Significance of the Electrical Conduction, Racemization and Halogen Replacement of Organic Halides in Solution, Dr. E. D. Hughes, Prof. C. K. Ingold and A. D. Scott, 120
Universities, Research and Teaching in, Prof. R. A. Peters, 590
Upper: Triassic Fossil Bed in Queensland, A New, Dr. R. J. Tillyard, 719; Atmosphere, Red and Sunlit Auroras and the State of the, Prof. L. Vegard, 930
Uranium and Thorium, Atomic Masses of, Prof. A. J. Dempster, 120
Valonia, Structure of the Wall of, Prof. G. van Iterson, jun., 364
Vernalization: Dr. F. G. Gregory and O. N. Purvis, 249; of Winter Rye during Ripening, Prof. F. G. Gregory and O. N. Purvis, 973
Vibrational Frequencies, Ground State, Dr. H. G. Howell, 36
Viscid Fluid Threads, The Nature of, Sir Joseph Larmor, 74
Viscosity of Binary Mixtures, Dr. A. J. A. Van der Wyk, 845
Vitamin: B_1 Deficiency, Role of Adenylic Acid in, Dr. T. W. Birch and Dr. L. W. Mapson, 27; P: Flavanols as Vitamins, S. Rusznyák and Prof. A. Szent-Gyorgyi, 27; A, Estimation of, J. F. Ward and R. T. M. Haines, 128; C, Inhibitive Effect of, on Toxin Production by *C. diphtheria*, I. J. Kligler, 291; B, Deficiency, Potassium in the Brain in, H. W. Kinnersley, 368; Nature of Flavones, A. Bentsáth, S. Rusznyák and Prof. A. Szent-Gyorgyi, 798; (C), Ascorbic Acid, Estimation of, by Titration, Dr. I. Gál, H Cheftel and Marie-Louise Pigeaud, 799; B_1, Hydrogenation of, F. Lipmann, 1097
Vitamins, Identification of, by Molecular Distillation, Dr. K Hickman, 881
van der Waals Forces, Determination of, Dr. H. S. W Massey and R. A. Buckingham, 77
Walden Inversion, Reaction Kinetics and the, W. A. Cowdrey, Dr. E. D. Hughes and Prof. C. K. Ingold, 759
von Waldeyer, Wilhelm, J. D. Boyd, 761
War: Scientific Workers and, Dr. E. Barrow and others, 80; Scientists and, Dr. C. N. Acharya, 469
Water, Moving, 'Lines' on the surface of, Dr. R. O. Hall, 466
Whale, Bones of a, from the Wieringermeer, Zuider Zee, Dr G C. A. Junge, 78
Whales, Antarctic Blue, The Stock of, A. H. Laurie, 33
Wheat, Occurrence of Haploid Pollen Mother Cells in a *vulgare*, Dr. R. M. Love, 589
Wireless Waves, Ultra Short, The 'Specific Action' of, Sir Leonard Hill and H. J. Taylor, 591; Prof. W. E. Curtis, Dr. F. Dickens and S. F. Evans, 1100
X-Radiation, An Effect of, on the Blood, Dr. H. L Brose and E. B. Jones, 687

Corrosion of Light Aluminium Alloys, Application of the Methods of Micro-chemical Analysis to the Study of the, H Fournier, 49
Cosmic: Ray Showers, Quantum-mechanical Theory of, W. Heisenberg, 42; Radiation, Bursts of, A. R. Hogg, 77; Rays: Extra-terrestrial Effects of, F. Zwicky, 91; Dr. W. F. G Swann, 209; Radiation: Specific Ionization of, M. G. E. Cosyns, 284; in the Upper Layers of the Troposphere, Continuity of the Variation of the, A. Ziemecki and K. Narkiewicz-Jodko, 301; Ray: Intensity: in a Deep Mine, Measurements of, Dr. J B. Barnóthy and Dr. M. Forró, 325; Intensity, Variation of, with Sidereal Time, Dr. B. F. J. Schonland, B. Delatizky and J. P. Gaskell, 325; Rays: Absence of, from Nova Lacertæ, Dr. J. Barnóthy and Dr. M. Forró, 544; Cloud Chamber Observations of, C. D. Anderson and S. H. Neddermeyer, 555; and Solar Activity, H. T. Graziadei, 562; Ray Burst at a Depth Equivalent to 800 m. of Water, A, Dr. Y. Nishina and C. Ishii, 721; Cyclotron, A, as a Cosmic Ray Generator? Prof. H. Alfvén, 761; Radiation, a Temporary Excess of Ten per cent in, J. Clay, E. M. Bruins and J. T. Wiersma, 812
Cosmology, The Observational Approach to, Dr. E. P. Hubble (Rhodes memorial lectures), 1001
Cotton: Haploids in, Dr. S. C. Harland, 334; Inheritance in, Dr. J. B. Hutchinson, 471; Hair, Development of the, Dr. F. M. L. Sheffield, 1062
County Natural History Societies, [1836], 257
Cow-Dung, Nitrogen Fixation with, Prof. N. R. Dhar and S. K. Mukerji, 1060
Cows' Milk, Phosphatase of, S. J. Folley and H. D. Kay, 767
Cozymase, Phosphorylation of, Mme. Dorothy Moyle Needham, 774
Cranial Muscles of Vertebrates, The, Prof. F. H. Edgeworth (*Review*), 221
Crater Lake, The Blue Water of, Dr. E. Pettit, 198
Crayfish (*Cambarus clarkii*) Muscle, Mechanism of Inhibition of, C. A. G. Wiersma and G. Marmont, 775
Creatinine, Reaction of, with 1,3,5-trinitrobenzol, 2,4,6-trinitrotoluol, and 2,4,6-trinitrobenzoic Acid, A. Bolliger, 813

Crop-Growing Without Soil, Prof. W. F. Gericke, 581
Crops and Livestock in England and Wales, 281
Crosse, Andrew, and his Electrical Experiments [1836], 519
Crustacea, L. Boone (*Review*), 385
Crystal: the Crystal Photo-effect and Rectifying Action in the Bulk of the, Dr. G. Groetzinger and J. Lichtschein, 163; Analysis. Structure-Factor Graphs for, Prof. W. L. Bragg, 362; Calculation of Structure Factors and Summation of Fourier Series in, Non-centrosymmetrical Projections, Dr. J. M. Robertson, 683; Analysis, Progress in the Technique of, Sir William Bragg, 953
Crystal Palace, Destruction of the, 961
Crystalline Substances, Liquid, from Virus-infected Plants, F. C. Bawden, N. W. Pirie, J. D. Bernal and I. Fankuchen, 1051
Crystals, Optical Phenomena of, [1836], 1026
Cultural and Social Values of Science, Sir Richard Gregory, Bt., 594; Prof. L. Hogben, 595; Sir A. D. Hall, 596
Culture, Science and, 479
Cuprous: Oxide, Electrical Conductivity of, Influence of the Gases of the Atmosphere on the, L. Dubar, 339; Complex, A Co-ordinated, F. G. Mann, D. Purdie and A. F. Wells, 978
Current Science, July, 358
Curve Fitting, Prof. R. A. Fisher, 934
Cyathocotyle, A new Strigeid Parasite in the Rare Genus, S. C. Verma, 589, 757
Cyclanic Series, Molecular Transformation in the, M. Tiffeneau and Mlle. J. Gutman, 897
Cyclohexane Rings, Multiplanar, Non-Existence of, Dr. R. D. Desai and Prof. R. F. Hunter, 548
'Cyclol' Molecules, Energy of Formation of, Dr. D. M. Wrinch, 241; F. C. Frank 242
Cyclones, Ascent of Air in, Dr. A. H. R. Goldie, 166
Cyclopropane, Raman Spectrum of, R. Ananthakrishnan, 123
Cytology: Experimental, International Congress of, Meeting at Copenhagen, 769
Czechoslovakia: Education in, 375; Institute of Hygiene of, Vitamins in the Diet of the Poor, 682; Bee Control in, 717

Dairy Science, A. L. Bacharach (*Review*), 625
Dams: Large, International Commission on, Congress at Washington, Dr. F. M. Lea, 768
Dana Report, No. 7: Quantitative Investigations on the Distribution of Macroplankton in Different Oceanic Regions, Dr. P. Jespersen, 45
Danish Pollen Diagrams, New Archæological Datings in, K. Jessen, 695
Dark Adaptation after Varying Degrees of Light Adaptation, C. P. Winsor and Anna-Betty Clark, 415
Dartford-Purfleet Tunnel, 459
Darwin: at St. Helena [1836], 47, Charles, and Entomology, Prof. G. D. Hale Carpenter, 88
Darwin's: Visit to the Galapagos Islands: Centenary of, Issue of Commemorative Stamps by Ecuador, Dr. W. T. Calman, 15; Reflections on Travel [1836], 560
Days! Those were Good, Reminiscences, late C. L. Schleich. Translated by B. Miall (*Review*), 663
Dead Sea, Life in the, Dr. B. Wilkansky, 467
De Bilt, Holland, Earthquake Records at, 109
'Degassing' by Electricity, 1090
Demographic Statistics, 1007
Denmark, Medicine in [1836], 177
Dental Caries and Diet, 956
Derbyshire Caves Exhibition, 962
Dermatophyte Fungi, Canadian Work on, 176
Desert Sand, Movement of, R. A. Bagnold, 855
Determinism and Man, Prof. H. Levy (*Review*), 6
Déterminisme et variabilité dans le comportement des organismes, Prof. W. J Crozier (*Review*), 99
Deuterium: Water, Equilibria in Salt Systems with, F. T. Miles, R. W. Shearman and Prof. A. W. C. Menzies, 121; Solid Hydrogen and, Density and Compressibility of, at 4·2° K, Miss H. D. Megaw and Prof. F. Simon, 244; Thermal Conductivity of, C. T. Archer, 286; Water, Vapour Pressure of, F. T. Miles and Prof. A. W. C. Menzies, 294; as an Indicator in Stereochemical Investigations, Use of, Prof. H. Erlenmeyer, H. Schenkel and A. Epprecht, 547; Helium, Hydrogen and, Thermal Properties of, A. Bijl, 723; Metallic Hydrogen and, Expansion Pressures of, A. R. Ubbelohde, 845; Oxide, Entropy of, E. A. Long and J. D. Kemp, 890
Deuteroethylenes, Plane Vibration Frequencies of Symmetrical, Provisional Computation of the, Prof. C. Manneback and A. Verleysen, 367
Devernalization of Winter Rye by High Temperature, Prof. F. G. Gregory and O. N. Purvis, 1013
Diamagnetism: and Particle Size, Prof. H. Lessheim, 848; of Mixtures of Organic Liquids, Prof. J. F. Spencer and Dr. V. C. G. Trew, 974
Diamond, Surface Markings on a, Dr. W. H. George, 616
Diastase in Rabbit Saliva, I. M. Thomas, 1015
Diatomic: Sulphur, Selenium and Tellurium Vapours. Dissociation Energy of, P. Goldfinger, W. Jeunehomme and B. Rosen, 205; Molecules, Constants of, Dr. N. R. Tawde, 649
Diatoms, Japanese, Dr. H. Aikawa, 1104
Dichlor-Diethyl-Sulphone, Effect of, on Brain Respiration, Prof. R. A. Peters, 327
Dielectric: Losses in an Alternating Field of High Frequency and Molecular Dimensions, J. Henrion, 339, Phenomena in High Voltage Cables, Dr. D. M. Robinson (*Review*), 633
Diesel: -Electric Traction on the Netherlands Railways, W. Hupkes, 174; Engines, Design of Fuel Injectors for, G. J. Lugt, 174; Fuel Specifications, C. H. Barton, 174; Fuels: and Engineering, 174; Ignition, Quality of, Correlation of Tests on the, carried out at Delft and Sunbury, G. D. Boerlage, J. J. Broeze, L. J. Le Mesurier and R. Stansfield, 174; Engines, High Speed: Maintenance of, A. W. Judge (*Review*), 527; with Special Reference to Automobile and Aircraft Types, A. W. Judge. Second edition (*Review*), 527
Dietary Standards, 810
Differential Equations, The Theory of (*Review*), 629
Diflavonols, Synthesis of, Prof. J. Algar, 300
Dilute Traces, Physiological Potency of, Sir Joseph Larmor, 929
3,5-Dimethoxybenzaldehyde, Derivations of, G. Lock and G. Nottes (5), 49
Dimethyl Ether, Influence of Nitric Oxide on the Thermal Decomposition of, Gaseous Catalysis, P. F. Gay and Prof. M. W. Travers, 546
Dinoflagellates of the Coastal Waters of the Western Pacific, Dr. A. Bohm, 935
Direction Finding by Sound, Dr. W. S. Tucker, 111
Dirhinini and Epitranini (Hymenoptera, Chalcididæ), Nearctic, B. D. Burks, 91
Disease in the Tropics, Prevention of, 71
Dissociable Organic Oxides and Anthracene Structure, C. Dufraisse and M. Gérard, 90
Distillation, Prof. J. Reilly (*Review*), 570
Doctors of the Nineteenth Century, Great, Sir William Hale-White (*Review*), 663
Dove Marine Laboratory, Report of the, 434
Drosophila: Male, A case of 50 per cent Crossing-over in the, D. Moriwaki; Dr. G. Eloff, 34; *pseuda-obscura*, Suppression of Tangled in, H. P. Donald, 48; *melanogaster*, *Y*-Chromosome in, Immunological Detection of the, Dr. S. G. Levit, S. G. Ginsburg, V. S. Kalinin and R. G. Feinberg, 78, *X*-Chromosome of, Dr. C. A. Offermann, 129; *melanogaster*, Two Unusual Modifications of Eye Colour in, Dr. E. V. Enzmann and C. P. Haskins, 165; Several Spontaneous Chromosome Aberrations in, Dr. S. L. Frolova, 204; Crossing-over in, Influence of Temperature on, H. Fairfield Smith, 329; *melanogaster*: Local, during late Larval Stage, Behaviour of, Dr. G. Eloff, 402; A case of Complete Reversion of a Chromosomal Rearrangement in, Dr. H. Gruneberg, 508; Effect of Temperature on the Frequency of Somatic Crossing-over in, C. Stern

and Violet Rentschler, 600 ; *pseudo-obscura*, Inversions in the Third Chromosome of Wild Races of, A. H. Sturtevant and T. Dobzhansky, 600 ; Imaginal Buds of the Appendages in, Dr. Charlotte Auerbach, 689 ; *pseudo-obscura*, Genetical Constitution of, H. P. Donald, 725
Dutrochet's Experiments in Vegetable Physiology [1836], 1111
Dyes in the Molecular State, Spectral Absorption and Fluorescence of, Dr. E. E. Jelley, 1009
Dynamics, Classical (*Review*), 264

Ear, Internal, Physical Nature of certain of the Vibrating Elements of the, C. S. Hallpike, Prof. H. Hartridge and Dr. A. F. Rawdon-Smith, 839
Early Man, Chronology of, and Cultural Associations, Sir Arthur Keith, 277
Earth : Down to, an Introduction to Geology, C. Croneis, and W. C. Krumbein (*Review*), 527
Earthquake : Records at De Bilt, Holland, 109 ; Japanese, of February 21, 1936, N. Nasu and T. Hagiwara ; N. Miyabe ; T. Saita, 171 ; Formosa, of April 21, 1935, Prof. N. Miyabe and others, 353 ; of April 6, 1580, The British, R. E. Ockenden, 472 ; Belluno, of October 18, 713 ; Epicentres, Catalogue of, Miss Ethel F. Bellamy, 766
Earthquakes : Lunar Periodicity of, M. W. Allen, 209 ; Tokyo, in 1935, 252 ; in California, Recent, P. Byerly and J. T. Wilson, 936 ; in the Kwanto (Japan) District, Distribution of, T. Nagata ; N. Nasu, T. Hagiwara and S. Omoti, 1063
Earth's : Rotation, Irregularity of the, N. Stoyko, 339 ; Magnetism, The, Prof. S. Chapman (*Review*), 1079
Earthworm, Respiration of the, Effect of Temperature on the, C. M. Pomerat and M. X. Zarrow, 91
East Africa, Taxation, Administration and Research in, W. G. A. Ormsby-Gore, 735
Echinoidea, A Monograph of the. 2 : Text and Atlas, Prof. T. Mortensen (*Review*), 344
Economic and Social Surveys, Need for Centralization of Information on, Prof. A. M. Carr-Saunders, 597
Economics, International, and Social Reconstruction, 341
Economists and the Public : A Study of Competition and Opinion, Prof. W. H. Hutt (*Review*), 1037
Edinburgh University : Prof. J. Ritchie appointed professor of natural history ; conferment of doctorates, 176 ; Dr. J. A. Kitching appointed lecturer in experimental zoology, O. A. Trowell lecturer in physiology, A. Brown full-time assistant in physiology, and Dr. F. Bath lecturer in mathematics, 1110
Edison, his Life, his Work, his Genius, W. A. Simonds (*Review*), 740
Education : The Future in, Sir Richard Livingstone, 456 ; Act, 1936, 558 ; The Future in, Sir Richard Livingstone, 601 ; for Rural Life, Sir John Russell ; H. Morris ; G. W. Pierce, 891
Educational Platform for 1936, An, 895
Eel-Grass Disease and Parasite on the American Atlantic Coast, Persistence of the, C. E. Renn, 507
Egg Cleavage, Geometrical Laws of, Monteil, 648
Egypt : Early Iron in, C. Hawkes, 592 ; Ancient, Royal Prowess in, 837
Egyptian, Ancient, Sculpture, 1005
Ehrenberg's Microscopical Discoveries [1836], 694
Einstein's Theory, A Fundamental Difficulty of, Minimal Lines and Geodesics within Matter, Dr. L. Silberstein, 1012
Eirene and *Helgicirrha*, The Medusæ, Dr. P. L. Kramp, 333
Elastic Modulus of certain Definite Intermetallic Compounds, A. Portevin and L. Guillet, jun., 476
Elasticity : Theory of : An Introduction to the, for Engineers and Physicists, Prof. R. V. Southwell (*Review*), 54 ; Prof. S. Timoshenko (*Review*), 54
Electrets, Experiments with, Dr. G. Groetzinger and H. Frei ; A. Gemant, 130
Electric : Heating of Garden Frames, Dr. J. Grainger and T. F. Armstrong, 251 ; Batteries, Industrial Use of, Dr. Strohe, 297 ; Supply in the Irish Free State, 397 ; and Magnetic Measurements, Principles of. Part 1 : Electricity, P. Vigoureux ; Part 2 : Magnetism, C. E. Webb (*Review*), 485 ; Lighting, Science and, C. C. Paterson, 515 ; Field, Movement of Growth-Promoting Substance and the Growth of Plants in an, V. Katunskij, 656 ; Services in Buildings, H. T. Young, 752 ; Currents in Metalliferous Veins [1836], 983 ; Illumination, Lord Rutherford ; Exhibition of, 1046 ; Discharge, Mechanism of Chemical Reaction in the, Dr. E. J. B. Willey, 1054
Electrical : Contacts, G. Windred, 41 ; Interference with Broadcasting, 181 ; 255 ; Engineering Supply, Day-load Peaks in, 372 ; Engineers, Institution of, awards of scholarships to W. E. Harper, P. Hargreaves, L. S. Arnand, D. H. Thomas, W. H. Penley, E. F. O. Masters and L. G. Leaton, 375 ; Accidents in 1935, Report on, 459 ; Power Station, New Fulham, 611 ; Measurements in Principle and Practice, H. C. Turner and E. H. W. Banner (*Review*), 635 ; Prospecting and its Uses, M. Schlumberger, 807 ; Saturation in Pure Liquids and their Mixtures, A. and B. Piekara, 943 ; Machinery Laboratory, Polytechnic, Regent Street, 1066
Electricity : Distribution in Great Britain, 69 ; in Horticulture, 70 ; Transmission and Distribution of, C. F. Bolton and R. H. Abell, 109 ; Experimental, M. M. Das (*Review*), 183 ; Supply, Progress in France of, 359 , Grid, Advantages from the, H. Hobson, 611
Electrification : Rural, in Great Britain, S. E. Britton, 500 ; of a Roof during a Thunderstorm, W. F. Tyler, 724
Electrochemistry : Experimental and Theoretical, Principles of, Prof. M. Dole (*Review*), 144 ; Principles and Applications of : Prof. H. J. Creighton. In 2 Vols. Vol. 1 : Principles. Third edition (*Review*), 144 ; Prof. W. A. Koehler. In 2 Vols. Vol. 2 : Applications (*Review*), 144 ; Theory and Practice of, Prof. J. Kendall (*Review*), 144
Electrolysis of Some Salts in Anhydrous Glycerol, M. Centnerszwer and J. Szper, 733
Electrolytes and a General Phenomenon in Tissue Cells, Prof. H. Grossfeld, 31
Electrolytic Oxidation : and Reduction : Inorganic and Organic, Dr. S. Glasstone and Dr. A. Hickling (*Review*), 144 ; Dr. A. Hickling, 937
Electronic Charge, X-Ray method for Determining, J. W. M. Du Mond and V. L. Bollman, 767
Electronics, Industrial, F. H. Gulliksen and E. H. Vedder (*Review*), 704
Electron Oscillator, A New, Prof. K. Okabe, 685
Electrons, Fast, through Matter, Passage of, H. J. Bhabha and Dr. W. Heitler, 401
Electroplating, Developments in, D. J. Macnaughtan and others, 707
Elements 72, 73, 75, 83, 90 and 92, Observation and Measurement of the *Lα* Satellites for the, Mlle. Yvette Cauchois, 216
Elephants : Body Temperatures of, F. G. Benedict and R. C. Lee, 415 ; Evolution of the (*Review*), 860
Ellsworth's Trans-Antarctic Flight, Topographical Results of, W. L. G. Joerg, 238
Elm Trees, Disease in [1836], 215
Emitters GeCL and GeBr, Ultra-Violet Band Systems of the, L. A. Bashford, Prof. H. V. A. Briscoe and Dr. W. Jevons, 883
Empire : Survey Officers, Conference of, 1935, 254 ; Surveys, 254 ; Fauna at Home and Abroad, 434 ; Co-operation in Agricultural Research, 777
Emulsions : Theory and Practice (*Review*), 702 ; Theory of, and their Technical Treatment, Dr. W. Clayton. Third edition (*Review*), 702
Enamel Protein, Dr. P. Pincus, 970
Encyclopædia, World, The Idea of a, H. G. Wells, 917
Endemic Flora of Britain, A. J. Wilmott, 89
Energy, Conservation of, and Shankland's Experiment, F. Cernuschi, 896
Engineer : Training of the, in the U.S.A., R. E. Hellmund, 174 ; and the Nation, Prof. W. Cramp, 453 ; 574 ; Training of the, Prof. C. J. Hawkes, 753

Engineering: Materials, Mechanical Tests for, A. M. Roberts, 852; and Empire Development, Sir Alexander Gibb, 1038
England: Northern, T. Eastwood, 390; South-west, H. Dewey, 390; and Wales, Population of [1836], 732
Engraulis encrasicholus L. (Anchovy), Influence of Hydrogen Ion Activity and of Salinity on the Eggs of, S. S. Elizarova, 561
Entomological Society [1836], 47, 598
Enzyme: Studies (*Review*), 141; Chemistry, Recent Advances in, Prof. E. Waldschmidt-Leitz, 409
Enzymforschung, Ergebnisse der, Herausgegeben von F. F. Nord und R. Weidenhagen. Band 5 (*Review*), 141
Enzymologia, Nos. 1 and 2, 612
Ephemeroptera, A Study of the, M. E. Mosely (*Review*), 223
Epidemiology, Experimental, Prof. M. Greenwood, Dr. A. B. Hill, Dr. W. W. C. Topley and J. Wilson, 474
Epithelioma Inoculated in the Eye, Intra-cutaneous Immunization of Rabbits against, A. Besredka and M. Bardach, 258
Ericsson's, John, Screw Propeller [1836], 90
Erosion, Normal, as a Factor in Soil Profile Development, G. Milne, 549
Eruca sativa Mill, Self-Sterility in, Z. Alam, 372
Eruptive Prominences, A Second Law of the Motions of, E. Pettit, 91
Eskimo: Chronology, F. G. Rainey, 378; Girls, Puberty in, A. Hrdlička, 378; Cultural Origins in East Greenland, P. V. Glob, 647
Essential Oils, Antiseptic Power, either Immediate or after Prolonged Action, of, J. Risler, 656
Esters, Action of Organic Acids on, H. Gault and A. Chablay, 855
Ethnology of the Far East, 876
Ethylene Molecule, Vibrations of the, S. Bhagavantam, 1096
Eucalypts, Differentiation of Varieties of, by their Essential Oils, A. R. Penfold and F. Morrison, 1099
Eucalyptus: *globulus* and *Eucalyptus Johnstoni*, Chromosome Number of, Prof. A. L. McAulay, F. D. Cruickshank and R. G. Brett, 550
Eugenics Society, J. C. Trevor awarded a Leonard Darwin scholarship, 756
Euphrates Expedition [1836], 177
Europe: A History of, H. A. L. Fisher (*Review*), 903; Mr. Fisher's History of, F. S. Marvin (*Review*), 903
European Civilization and the African (*Review*), 947
Evolution: Hormones and, Dr. S. Zuckerman, 408; Atrophy, Burial, Suppression or Total Loss in, Prof. H. A. Harris, 928
Examinations, Essays on, Sir Michael Sadler and others (*Review*), 820
Examiners, The Marks of, Sir Philip Hartog and Dr. E. C. Rhodes. With a Memorandum by Prof. C. Burt (*Review*), 820
Experience, Patterns of, A. W. Wolters, 455
Experimental Psychology at Oxford, The Institute of, Dr. W. Brown appointed director and Dr. W. Stephenson assistant director, 14

Faeroes, Geology of the, F. Walker and C. F. Davidson, 178
Fahrenheit, Daniel Gabriel (1686–1736), 428
Fairthorne-Salt Mathematical Film, R. A. Fairthorne and B. G. D. Salt, 726
False-Killer Whale: in Scotland, 408; in South Africa, Dr. L. Gill, 541
Faraday: *House Journal*, 755; Letter, A, London University Degrees, 710
Fatty Acids in Organic Mixtures, Estimation of, E. R. Hiscox and J. Harrison, 32
Feathers, Bilateral Gynandromorphism in, P. G. 'Espinasse 645
Fermente, Die, und ihre Wirkungen, Prof. C. Oppenheimer. Suppt., Lief 4 (*Review*), 269
Ferns, Apospory in, A New Type of, Misses I. Andersson-Kottö and A. E. Gairdner, 471
Feulgen Reaction of the Bacteriophage Substance, The, Dr. M. Schlesinger, 508
Fibre Studies, W. T. Astbury and others, 824
Fibres, Chemistry of, 175
Field Concept, Morphogenesis and the, C. H. Waddington, 809
Fiji, Mosses of, E. B. Bartram, 554
Films: and their Utilization, 239; Educational, 983
Filterable Organisms, New Group of, Sir Patrick Laidlaw and W. J. Elford, 648
Finance, Research and, 51
Fireball: over Yorkshire, 360; Bright, of November 14, 965
Fire-Fighting in America, History of, 197
Fish: and Fishing (*Review*), 308; Resistance of, to Supercooling, P. J. Schmidt, 977
Fishes, A Book of (*Review*), 57
Flagella Movement, A. G. Lowndes, 210
Flavanols as Vitamins, Vitamin P: S. Rusznyák and Prof. A. Szent-Gyorgyi, 27
Flavins in Normal Human Urine, Determination and Excretion of, A. Emmerie, 164
Flavones, Vitamin Nature of, A. Bentsáth, S. Rusznyák and Prof. A. Szent-Gyorgyi, 798
Flavours and Essences: A Handbook of Formulæ, M. H. Gazan (*Review*), 949
Floras, Native, Preservation of, Dr. A. B. Rendle, 457
Flour Beetles of the genus *Tribolium*, N. E. Good, 129
Fluorescence of Some Pure Substances, E. Canals and P. Peyrot, 1026
Fluorescent Substances, Photo-Reduction of, by Ferrous Ions, Dr. J. Weiss, 80
Fluorite and Rock Salt, Coloration of, E. Eysank, 415
Food: Requirements in the Modern State, 379; Science, Chemistry and, Dr. L. Harris and others, 744; Preparation of, Dr. L. H. Lampitt, 745; Transport, T. Herbert, 745; Science, The Analytical Chemist and, Dr. G. R. Lynch, 746; and the Family Budget, 753; Production, Consumption and Prices, Statistics of, 765; Investigation: a Retrospect and the Future, 825; Board, Report of the, for the Year 1935, 825; and the Principles of Dietetics, Dr. R. Hutchison and Prof. V. H. Mottram. Eighth edition (*Review*), 994
Foraminifera, A Suggested Classification of the, F. Chapman and W. J. Parr, 520
Forbes, J. D., and Auguste de la Rive [1836], 559
Force and Matter, Unity of, Dr. J. Bašta, 83
Forest and Forest Industries of the Prairie Provinces, J. D. B. Harrison, 1091
Forestry in Kenya, 253
Forests and Forestry in Trinidad and Tobago, R. L. Brooks, 926
Formosa Earthquake of April 21, 1935, Prof. N. Miyabe and others, 353
Formosan Tea Leaves, Tannin substance of, Y. Ōshima, 695
Forth, A Vertebrate Fauna of, Leonora Jeffrey Rintoul and Evelyn V. Baxter (*Review*), 703
Forthcoming Books of Science, 637
Fossil: Human Skull, A New, from Swanscombe, Kent, Preliminary note on, A. T. Marston, 200; Anthropoid Skull from South Africa, New, Dr. R. Broom, 356; 486, 498; Horse Remains from Idaho, C. L. Gazin, 512; Men of Engis, Dr. C. Fraipont, 553; Human Remains from Kanam and Kanjera, Kenya Colony, Dr. L. S. B. Leakey, 643; Skull, A New, from Eyassi, East Africa, Discovery by a German Expedition, Dr. L. S. B. Leakey, 1082
Fossils: on the Continent, Discovery of [1836], 413; of the Late Pre-Cambrian (Newer Proterozoic) from the Adelaide Series, South Australia, Memoir on, late Sir T. W. Edgeworth David and Dr. R. J. Tillyard (*Review*), 994
Fourier Series in Crystal Analysis: Calculation of Structure Factors and Summation of, Non-centrosymmetrical Projections, Dr. J. M. Robertson, 683
Fowl Paralysis, Leaflet on, 797

France d'outremer, Les ressources minérales de la. 3: Le zinc, le plomb, l'argent, le cuivre, l'or, les minerais radioactifs, le mica, les pierres précieuses, substances diverses. 4: Le phosphate (*Review*), 265
Franklin Institute, Biochemical Research at the, 23
Free Will, Indeterminism and, Prof. E. Schrodinger, 13
Friction of a Solid Moving in Water, E. Brun, 1111
Fritz, John, gold medal, award of the, to Prof. A. N. Talbot, 1002
Frost Hardening, J. Levitt and G. W. Scarth, 806
Fruit: Juice Factory, A New, 157; Supplies in 1935, 296
Frustration: The Anatomy of, a Modern Synthesis, H. G. Wells (*Review*), 779
Fungi: and Graft Unions, T. E. T. Bond, 40; Irish, P. O'Connor, 338, 1020; Uses of, J. Ramsbottom, 455; Positive Economics of the, J. Ramsbottom, 746; Researches on, Prof. A. H. R. Buller. Vol. 6 (*Review*), 1033; Wood-Decaying, Heat-Treatment for, H. B. S. Montgomery, 1104
Futuna, Ethnology of, E. Burrows, 647

γ-Radiations, Measurement of, Dr. G. W. C. Kaye, 606
γ-Radioactivity, Continuous, and Unitary Field Theory, E. C. G. Stueckelberg, 259
γ-Ray Intensities from Radium Preparations, Comparison of, J. A. C. Teegan, 338
Galaxies, The Background of the, Prof. E. A Milne, 38
Gallic Acid, Raman Spectrum of, of some of its Derivatives and of Tannin, B. Susz and S. Fried, 259
Gambart, Jean-Félix-Adolphe, Death of [1836], 137
Gardener, The Junior, Harriet Price. Edited by Walter P. Wright (*Review*), 784
Gas: Reactions: Kinetics of, an Attempt to connect Thermal Decomposition and Oxidation Processes, Prof. M. W Travers, 26; Attacks: Is there any Protection ?, 360
Gaseous: Isotopes, Separation of, by Diffusion, D. E. Wooldridge and W. R. Smythe, 555; Combustion, Prof. W. T. David, 930; Organic Compounds, Mechanism of Thermal Change in, Prof. M. W. Travers, 967
Gases, Explosive, Ignition of, G. Mole, 1063
Geckos of Japan, Y. Okada, 765
Gefasserweiternde Stoffe der Gewebe, Prof. J. H. Gaddum. Eingeleitet von H. H. Dale (*Review*), 267
Geiger-Muller Counters, Steady Performance of, Prof. B. Dasannacharya and G. S. Rao, 289
Genetic Ideas, Racial Theory and, Prof. H. J. Fleure, 1042
Genetics: and Ecology in Relation to Selection, Dr. J. S. Huxley and others, 748; and Race, 988; in the Universities, Dr. E. Ashby, Prof. F. A. E. Crew, Dr. C. D. Darlington, E. B. Ford, Prof. J. B. S. Haldane, Prof E. J. Salisbury, Dr. W. B. Turrill and C. H. Waddington, 972; Prof. W. Neilson Jones, 1058
Geodesy and Geophysics: International Union of, General Assembly at Edinburgh; Dr. D. la Cour elected next president, 650
Geographical Magazine, December, 1007
Geographical Review, Index to the, 796
Geography: and Distribution (*Review*), 782; Plant and Animal, late Dr. Marion I. Newbigin (*Review*), 782; an Introduction to Human Ecology, Prof. C. Langdon White and Dr. G. T. Renner (*Review*), 1075; Elements of, Prof. V. C. Finch and Prof. G. T. Trewartha (*Review*), 1075; New, Foundations of the (*Review*), 1075
Geological: Survey of Great Britain, Summary of Progress of the, 1933, 373; Survey and Museum: New Activities, 433
Geologiska Foreningen, Stockholm, Prof. P. Ramdohr elected a member of the, 1093
Geology: and the Community, Dr. Dighton Thomas, 89; in Great Britain, 373; British Regional, 389
Geometry, Intrinsic, of Ideal Space, Prof. A. R. Forsyth. 2 Vols. (*Review*), 343
Geomorphology of the Irish Sea Basin, Prof. J. Kaye Charlesworth, 1040
Geophysics of the Indo-Pacific Region, Lt.-Col. R. B. S. Sewell (*Review*), 419
Geophysik, Handbuch der, Herausgegeben von Prof. B. Gutenberg. Band 1, Lief 3: Breitenschwankungen, von Prof. W. D. Lambert; Theorie des irdischen Schwerefeldes, von Prof. E. A. Ansel. Lief 4 (Schluss des Bandes): Beobachtung der Schwerkraft; Die Lotabweichungen; Das Problem der Isostasie. Von Prof. W. Heiskanen (*Review*), 784
German: Philosophy, Contemporary, An Introduction to, Dr. W. Brock (*Review*), 269; Road Progress, Dr. O. R Eismann, 280; Bunsen Society, Prof. M. Bodenstein awarded the Bunsen medal; Prof. M. Le Blanc elected an honorary member, 282; Research Institute of Psychiatry, Prof. W. Scholz appointed director of the department of Cerebral Pathology of the, 361; Statistical Society, Prof. S. Schott, Dr. F. Prinzing, Dr. Kovacs and Dr. Savorgman nominated honorary members, 361, Academy of Naturalists, Halle, Dr. H. R. Mill elected a member of the, 460; Chemists at Munich, 475; Chemical Engineering, 500; Naturalists, Association of [1836], 518; Chemists, Association of, Prof. H. von Euler-Chelpin elected an honorary member of the; award of the Justus Liebig medal to Prof. G. Hittig and the Carl Duisberg memorial prize to Dr. R. Tschesche, 543; Society of the History of Medicine, Natural Science and Technique, award of the Sudhoff medal to Prof. R. Zaunick, 718
Giraffes at the Zoological Gardens, London [1836], 216
Girard, Pierre-Simon, 1765–1836 [1836], 942
Glasgow University: grant from the Bellahouston Bequest Fund; Prof. G. Cook appointed regius professor of civil engineering; Prof. J. S. Dunn elected professor of pathology and Dr. H. B Cott appointed lecturer in zoology, Dr. J. Dougall to deliver the Gibson lecture for 1936–37, 46; Dr. J. W. McNee appointed regius professor of the practice of medicine; gifts from Prof. J. Graham Kerr and Prof. F O. Bower; L. H. Littlejohn awarded a Colonial agricultural research scholarship, 731, Dr. W. M. Smart elected regius professor of astronomy; O. S. Franks elected professor of moral philosophy; Dr. J. Dougall appointed Gibson lecturer in the history of mathematics; gifts by Sir Frederick Crombie Gardiner and the trustees of the late W. G. Gardiner, 895
Glasshouse Industry, Science and the, Dr. W. F. Bewley, 556
Glass Melts, Relative Abundance of Potassium and Lithium Isotopes and the Emission of Alkali Ions from, H Bondy and V. Vanicek, 49; Phosphorescent, M. Curie, 1026
Globular Clusters, Colours of, Stebbins and Whitford, 890
Gluconic Acid, Antiscorbutic Activity of a Derivative of, Prof. B. A. Lawrow, Prof. W M. Rodionow, E. M Bomdas and N. S. Jarussowa, 40
Glutathione, Reduced, The Nitroprusside Reaction as a Test for, N. S. R. Maloeuf, 75
Glycols, Monochlorhydrins of, Mechanism of the Formation of the, H. Moureu and M. Dodé, 897
Godthaab Expedition, Crustacea from the, Dr. J. Stephensen, 848
Goethe medal, award of the, by the Chancellor of the Reich to Prof. F. Hueppe, 797
Gold: in Sea-Water, Presence of, G. Claude, 138; -Copper Alloys, Anodic Behaviour of, in $5N$ Hydrochloric Acid and N Sulphuric Acid, W. J. Müller, H. Freissler and E. Plettinger, 218
Gold Coast Survey, Report of the, for 1935–36, 1092
Gondwana Affinities of the Angara Flora in the light of Geological Evidence, The, Prof. B. Sahni, 720
Gorilla, Coast, Distribution of, H. J. Coolidge, jun., 1019
Government Laboratory, Work of the, 730
Graham's Work on the Constitution of Salts [1836], 983
Gramophone Record, The, H. C. Bryson (*Review*), 637
Grampian Highlands, The, H. H. Read, 391
Graphical Solutions, Prof. C. O. Mackey (*Review*), 864

Grassland of Great Britain, Prof. R. G. Stapledon, 875, 927
Gravitational Field of a Distribution of Particles Rotating about an Axis of Symmetry, W. J. van Stockum, 896
Gravity Measurements in Sweden, Dr. G. Ising and Dr. T. Eeg-Olofsson, 889; Dr. G. S. Ljungdahl, 890
Gray on Museums of Natural History [1836], 773
Graz University, Prof. Max Planck nominated an honorary doctor by, 361
Great Britain, Local Botany in [1836], 854
Greek Academy of Sciences, Arts and Letters, Dr. M. C. Balfour awarded the silver medal of the, 24
Greenkeeping Research, 398
Greenland: A Norse Settlement of the Viking Age in (*Review*), 948; Viking Settlers in, and their Descendants during Five Hundred Years, Dr. P. Norlund (*Review*), 948
Gresham Lecturers, The [1836], 984
Grosse Moos im westschweizerischen Seelande und die Geschichte seiner Entstehung, Das, W. Ludi (*Review*), 187
Growth: Substance *B*, Chemistry of, N. Nielsen and V. Hartelius, 203; Hormones and Development of Plants, Prof. N. G. Cholodny, 586
Guatemala, Maya Culture in the Highlands of, 892
Gulf Stream, An Ecological Aspect of the, Dr. A. C. Redfield, 1013
Gunther's Catalogue of Fishes in the British Museum, Re-issue of, 1092
Gurney, Sir Goldsworthy, and his Steam Carriages [1836], 137
Gypsies, Serbian, Marriage among, Dr. A. Petrović, 847
Gyroplanes, Possibilities of Speed and Radius of Action of, L. Breguet, 48

Hadrian's Wall, Excavation of, 108
Hæmoglobin, Ultra-Violet Absorption Spectrum of, G. A. Adams, 368
Half-Castes and World Peace, C. Dover, 432
Hamburg University, gold medal of the, award of the, to Prof. Nocht, 927
Hammond Organ, The, Sir James Barrett, 297
Hancock's, Walter, Steam Carriages [1836], 519
Happiness for Humanity: The Way to, a Modern Philosophy for Everyone, "Amator" (*Review*), 636
Hardness Tester for Microscopical Objects, A, Dr. E. M. H. Lips and J. Sack, 328
Harpacticids, Northern, K. Lang, 647
Harvard: University: Tercentenary Celebrations, The, 667, 679; Gift to, by Sir Robert Hadfield, Bt., 1005; award of the Squibb fellowship to W. P. Campbell, 1093
Harvey, The Background to (Harveian oration), Sir Walter Langdon-Brown, 833
Hatton Garden, Historical Memorial in, 194
Hawke's Bay Earthquake of February 2–3, 1931, Focal Depth of the, R. C. Hayes, 126
Health. Services, London, 110; National, Physique, Nutrition and, 857; Dr. James Johnson on [1836], 1068
Heat: and Work, Relation between, J. N. Brønsted, 774; Engine Idea in the Seventeenth Century, Rhys Jenkins, 794; for Advanced Students, late E. Edser. Revised edition by N. M. Bligh (*Review*), 952
Heating: and Lighting Appliances, Ancient, 71; in a Vacuum or in Air, Transformations produced in certain Metals by, J. J. Trillat and S. Oketani, 1069
Heavens, The, and Faith, Rev. M. Davidson (*Review*), 227
Heavy Nuclear Particles, Interaction of, D. Iwanenko and A. Sokolow, 246
Heidelberg and the Universities of America, 853
Helgicirrha, *Eirene* and, The Medusæ, Dr. P. L. Kramp, 333
Helisoma corpulentum and its Relatives in Canada, F. C. Baker, 889
Helium: Argon, Neon, J. T. Randall, 191; Radio-, Dr. T. Bjerge, 400; β-Ray Spectrum of, Dr. T. Bjerge and Dr. K. J. Brostrom, 400; II, Liquid, Optical Experiments on, L. W. Shubnikov and A. K. Kikoin, 641; Hydrogen and Deuterium, Thermal Properties of, A. Bijl, 723; Liquid, Latent Heat of, Evaporation of, Dr. J. Newton Friend, 1102; produced in Artificial Transmutation, Prof. F. A. Paneth, E. Gluckauf and H. Loleit, 1105
Henry, Dr. William, Death of [1836], 376
l'Hérédité, Les conceptions modernes de, Prof. M. Caullery (*Review*), 633
Heredity and the Ascent of Man, Dr. C. C. Hurst (*Review*), 743
Herkunftsbestimmung bei Honig, Beiträge zur. Band 1, Prof. E. Zander (*Review*), 147
Herpetologia, No. 1, 582
Herschel: Sir John, and Mr. Somerville [1836], 90; Effect, Dependence of the, upon the Surrounding Gas Medium, Mrs. A. Vnukova, 246; Caroline, and Sir John Herschel [1836], 694
Hexlet, The, Prof. F. Soddy, 958
High: -Frequency Systems, Phenomena in, A. Hund (*Review*), 9; -Voltage Impulses at Controllable Speed, Transmission of, Dr. L. B. Snoddy, Prof. J. W. Beams, W. T. Ham, jun. and H. Trotter, jun., 167; Voltages, Production and Technical Application of, 605
Highway Engineering, The Science of, Prof. R. G. H. Clements (*Review*), 951
Himalayan Uplift since the Advent of Man, Prof. B. Sahni, 847
Histone Insulinate, Hypoglycæmic Action of, A. Biasotti, V. Deulofeu and J. R. Mendive, 1101
History, General, The Place of Science in, 575
Homœopathy, Doctrine of [1836], 773
Honey, Heather, Physical Properties of, J. Pryce-Jones; Dr. G. W. Scott, Blair and D. Morland, 770
Horizon, The Receding (*Review*), 859
Hormones: and Evolution, Dr. S. Zuckerman, 408; and Horticulture, Dr. M. A. H. Tincker, 766
Horse Hæmoglobin, Total Dissociation of, Dr. J. Steinhardt, 800
Horticultural: Colour Chart, A, 322; Research: Recent Advances in, East Malling Research Station; Long Ashton Research Station; Cheshunt Research Station, 850
Horticulture, Electricity in, 70
Hospitals and Sanatoria, Costing Returns of, 398
Hudson Strait Survey, 806
Hufeland, Christoph Wilhelm, 1762–1836 [1836], 338
Human: Progress, Concerning, Dr. H. S. Harrison, 20; Life, The Planning of, 139; Progress, Concerning, Dr. H. S. Harrison, 188; Heredity, Bureau of, 460; Tendencies, 521; History and Geographical Discovery, J. W. Mackail, 613; Behaviour, The Psychology of, Prof. J. H. Griffiths (*Review*), 823
Humboldt's Plan in 1836 for a World Magnetic Survey, 894
Humus: Origin, Chemical Composition, and Importance in Nature, Prof. S. W. Waksman (*Review*), 624; Soil, Nature and Functions of (*Review*), 624
Hydrazine and its Hydrate, Raman Spectrum of, L. Kahovec and K. W. F. Kohlrausch, 562
Hydrocarbons: Cyclic, Relations between the Baeyer Tension τ and the Characteristic Raman Frequency in the case of the, M. Aubert, 812; Explosive Combustion of, Influences of Dilution on the, Prof. W. A. Bone and L. E. Outridge, 942
Hydrocephalus (*hy*), in the House Mouse, *Mus musculus*, Linkage Relations of, F. H. Clark, 775
Hydro-Electric Development, Britain's Largest, 19
Hydrogen: Halide Gases, Optical Polarization Ellipsoids of the, Dr. C. H. Douglas Clark, 126; Solid, and Deuterium at 4·2° K., Density and Compressibility of, Miss H. D. Megaw and Prof. F. Simon, 244; Halide Gases, Kerr Constants of the, Dr. C. H. Douglas Clark and Dr. E. C. Humphries, 248; Isotopes, Temperature Coefficient of the Electrolytic Separation of the, H. F. Walton and J. H. Wolfenden, 468; Helium and Deuterium, Thermal Properties of, A. Bijl, 723; Peroxide, Use of Concentrated, for the Determination of the Mineral Content of Plant and Animal Materials, W. Vorbrodt, 733; Bond, The, and the Structure of Proteins, Drs. D. M. Wrinch and

D. Jordan Lloyd, 758; Inhibition by, of the Chain Reaction of Mixtures of Normal Pentane and Oxygen, M. Prettre, 774; Metallic, and Deuterium, Expansion Pressures of, A. R. Ubbelohde, 845
Hydrogenation of Coal: a French Process, F. Vollette, 473
Hydroids from the West Indies, Dr. E. Leloup, 409
Hydrostatics: a Text-book for the use of First Year Students at the University and for the Higher Divisions in Schools, A. S. Ramsey (*Review*), 386
Hygiene, Proposed Foundation in Japan of a Museum of, 72
Hymenoptera: Tetraploid ?, Are, B. R. Speicher, 78; Tetraploidy and, F. Greenshields, 330

Ice: Heat Capacity of, W. F. Giauque and J. W. Stout, 334; Ages, Causes of, G. H. Halligan, 813
Illuminating Engineering Society, award of the Gaster memorial premium to R. G. Hopkinson and of the Silver Jubilee Commemoration award to W. R. Stevens, 615
Illumination: Recommended Values of, 238; Progress in, 715; Research at the Science Museum, 1107
Imperial: Leopold Caroline German Academy of Science, election as members of Prof. P. Buchner, Prof. H. Loescheke, Prof. C. G. A. Forsell, Prof. S. E. P. Haglund, Prof. K. Faber, Prof. A. H. M. J. Van Rooy, Dr. E. Leclainche and Prof. K. Wegelin, 160; Institute, Advisory Council of the, on Mineral Resources, gift to, by Sir Robert Hadfield, Bt, 718; Leopold Caroline German Academy of Natural Philosophers, Halle, Prof. W. Heubner elected an honorary member of the, 797; Agricultural Bureaux, Seventh Annual Report, 1048; Cancer Research Fund, Thirty-fourth Annual Report 1935–36, 1085
Indeterminism: and Free Will, Prof. E. Schrödinger, 13; and Psychology (*Review*), 99
Index Generalis. Année 16, 1936 (*Review*), 100
India: Meteorology in, 70; Meteorology for Airmen in, 108; Survey of, General Report for 1935, 237; Cotton Research in, 359; Social Origins in, K. P. Chattapadhyay, 408; and Mineral Development, Sir Edwin Pascoe (*Review*), 621; Zoological Survey of, Report for 1932–35, 836; National Institute of Sciences of, Prof. F. G. Donnan and Sir Albert Seward elected honorary fellows of the, 879
Indian: Institute of Science, Bangalore, 42; Crop Plants, Physiology of, 70; Vital Statistics for 1933, 159; Conjuring, Lt.-Col. R. H. Elliot, 425; *Science Abstracts*, No. 1, 543, 916; *Wild Life*, 614; Association for the Cultivation of Science, Report for 1935, 717; South, Blood Groups, A Aiyappan, 888; Temple Architecture, Outline of, Dr F. H Gravely, 935; Institute of Science, The, 945; Institute of Science, Report of Quinquennial Reviewing Committee, 981
India's Mineral Wealth: a Guide to the Occurrences and Economics of the Useful Minerals of the Indian Empire, Dr. J. Coggin Brown (*Review*), 621
Indischen und Stillen Ozeans, Geographie des, Prof. G. Schott. Mit einem beitrag von Prof. E. Hentschel und Dr. W. Schott (*Review*), 419
Indium, F. M. Brewer and E. Baker, 890
Indo-China, Archæology in, Dr. H. G. Q. Wales, 795
Inductive Capacity Apparatus, Specific [1836], 1068
Industrial Development in South Africa and Facilities for the Establishment of Factories. Edited by Dr. V. Bosman, 256
Industry: Sickness Absence Wastage in, May Smith and Margaret Leiper, 408; Labour Wastage in, Prof. M. Greenwood and May Smith, 408; and the Profession of Chemistry, Relations between, M. P. Appleby, 557; Leadership in, 563; Administration and Technology in, 653
Infection and Disinfection, Modern views on, Sir Weldon Dalrymple Champneys (Chadwick lecture), 1046
Infra-red Absorption Spectra and the Modes of Vibration of Organic Compounds, J. Lecomte, 138
Inheritance in Man, Two-factor, Dr. Madge T. Macklin, 847
Inoculation against Colds, Post Office Tests of, 916
Insect: Metabolism, Humidity and, K. Mellanby, 124; Life of Temporary Rain Swamps in British Guiana, F. A. Squire, 151; Pests and Crops in England and Wales, J. C. F. Fryer and others, 212; Coloration, Prof. H. E. Armstrong, 242; Prof. G. D. Hale Carpenter, 243; Pests of Glasshouse Crops, Dr. H. W. Miles and Mary Miles. Edited by H. C. Long (*Review*), 348; Coloration and Natural Selection, Prof. E. W. MacBride, 365; Prof. G. D. Hale Carpenter, 686
Insecticide by Shot-Gun, Distribution of, 23
Institute of Metals, Paris meeting of the, 691
Insulating Material, A New, 593
Insulation Testing, 50 Cycle Wave-forms in, N. H. Roberts, 813
Insulators, Overhead Line, C. H. W. Clark, 1048
Insulin: its Production, Purification and Physiological Action, D. W. Hill and Dr. F. O. Howitt (*Review*), 56
Integral Calculus, Fox Talbot on the [1836], 854
Intensities, Sensory Discrimination of, W. J. Crozier, 415
Intensity Discrimination, Auditory, M. Upton and W. J. Crozier, 415
Intermedin, Action of, on Crustacean Melanophores and of the Crustacean Hormone on Elasmobranch Melanophores, A. A. Abramowitz, 775
International: Congress of the History of Science, Forthcoming, 323; Economics and Social Reconstruction, 341; Botanical Congress, Sixth, 396; Peace Congress, Science at the, C. Dover, 516; Union of Geodesy and Geophysics: General Assembly at Edinburgh; Dr. D. la Cour elected next president, 650; Relations promoted by Broadcasting, 678; Quaternary Association, Conference in Vienna, 692; Cancer Congress, Second, 727; Commission on Large Dams: Congress at Washington, Dr. F. M. Lea, 768; Congress of Experimental Cytology: Meeting at Copenhagen, 769; Astronomical Union, Transactions of the. Vol. 5: Fifth General Assembly held at Paris, July 10 to July 17, 1935. Edited by Prof F. J. M. Stratton (*Review*), 902; Studies Conference, Permanent, 915; Statistical Institute, Prof. F. Zahn nominated president of the, 1008
Invention, Science of, C. W. Marshall, 539
Inverse Diene Synthesis, Kinetics of an, in the Pure Liquid State, B. S. Khambata and A. Wassermann, 368; A. Wassermann, 369
Invertase and Dyestuffs, J. H. Quastel and E. D. Yates, 690
Iodine, First Spark Spectrum of, Anomalies in the Fine Structure of the, Dr. K. Murakawa, 324
Ion Formation, Negative, A New Process of, Dr. F. L. Arnot, 162
Ionization Current, Measurement of, Dr. F. E. Lea, 1024
Ionosphere: at Allahabad, Collisional Friction Frequency in the, G. R. Toshniwal, B. D. Pant and R. R. Bajpai, 37; Russian Eclipse Measurements on the, Prof. W. Kessenich, 195; The Lower Regions of the, Prof. R. C. Colwell, A. W. Friend, N. I. Hall and L. R. Hill, 245; Some Observations on the *C* Regions of the, Dr. H. Rakshit and J. N. Bhar; Prof. S. K. Mitra, 283
Ions, High Velocity Positive, Dr. J. D. Cockcroft (Mackenzie Davidson memorial lecture), 1025
Ipswich Museum, Special Exhibit at, 357
Iraq, Archæological Finds in, Dr. H. Frankfort, 279
Ireland, Flora of [1836], 376
Irish: Free State, Electricity Supply Board of the, Annual Report, 397; Sea Basin, Geomorphology of the, Prof. J. Kaye Charlesworth, 1040
Iron: A Radioactive Isotope of, Prof. E. B. Andersen, 76; Wire and Nerves, 83; Properties of (*Review*), 96; The Metal—, H. E. Cleaves and J. G. Thompson (*Review*), 96; and Molybdenum, Distortion of, Dr. E. W. Fell, 760
Islands, Odyssey of the, C. N. Taylor (*Review*), 348
Isomeric *bis*-Thiocamphors, Synthesis of Two, Sir P. C. Rây, 548
Isopod Crustacea, American Land and Fresh-Water, W. G Van Name, 554

Isotopes: and Molecular Asymmetry, Dr. T. Iredale, 292; Exchange Reactions with, E. Ogawa, 294
Isotopic Weights by the Doublet Method, Dr. F. W. Aston, 1094
Isturitz, The Cave of, A Magdalenian Site of Southern France, 1023
Italy, Land-Reclamation in, C. Longobardi, translated by Olivia Rossetti Agresti, Sir John Russell (*Review*), 4

Jabo Proverbs from Liberia: Maxims in the Life o a Native Tribe, G. Herzog, with the assistance of C. G. Blooah, 905
Japan: National Research Council of, Report, April 1934—March 1935, 502; Geckos of, Y. Okada, 765; Decline in Birth-rate, 838
Japanese Brachyura, T. Sakai; K. Koba, 1062
Jounnet: Grand-père de la Prehistoire, Dr. A. Cheynier (*Review*), 823
Jumna Valley, Antiquities of the, Prof. B. Sahni, 82
de Jussieu, Antoine-Laurent, Death of [1836], 476
Jute Industry, Research and the, Dr. G. S. Barker, 322; 581

$K\alpha_{1,2}$-Doublet of some of the Lighter Elements, Effects of Chemical Combination with Oxygen and Fluorine on the, Dr. N. G. Johnson, 1056
Kaiser Wilhelm Institute of Biochemistry, Berlin–Dahlem, Prof. A. Butenandt appointed director of the, 838
Kaiserlich Deutsche Akademie der Naturforscher, Halle, Prof. S. Chapman elected a member of the, 756
Karri Timber, Testing Green, I. Langlands, 170
Kātkāris: The, A Sociological Study of an Aboriginal Tribe of the Bombay Presidency, A. N. Weling (*Review*), 100
Kauri, Properties and Uses of, A. R. Entrican, 158
Keilin's Cytochrome c and the Respiratory Mechanism of Warburg and Christian, H. Theorell, 687
Kelvin, Bust of, for the Smithsonian Institution, 579
Kenya, Annual Forest Report for 1934, 253
Kepler, Collected Works of (*Review*), 422
Kepleriana, Bibliographia, unter mitarbeit von Dr. L. Rothenfelder. Herausgegeben von Prof. M. Caspar (*Review*), 422
Keramosphaera Brady, Genus, E. Heron-Allen, 689
Keratins, Cross-Linkage Formation in, Dr. H. Phillips, 121; Dr. J. B. Speakman, 327
Kerr Constants of the Hydrogen Halide Gases, Dr. C. H. Douglas Clark and Dr. E. C. Humphries, 248
Ketones, Aldehydes and, Photodecomposition of, Dr. R. G. W. Norrish and C. H. Bamford, 1016
Kew, Royal Botanic Gardens, New Exhibits, 1090
Kidney Phosphatase, Inhibitory Effect of Phloridzin and Phloretin on, Dr. H. Kalckar, 289
Kikuchi Lines: from Etched Copper Crystal, Dr. W. Cochrane, 202; Theory of, Studied by means of Models, A. Lichtenfeld and K. Schwarz, 218
Kincardine-on-Forth Bridge, Opening of the, 794
Kinematography, Exhibition of, 963
King's College, London, Medical Museum at [1836], 559
Kingship and Kinship, 1029
Knowledge: Use of, Sir James Irvine, 67; Unified, The Service of, 899
Kristallometrie, Kursus der, late Prof. V. Goldschmidt. Herausgegeben von Dr. H. Himmel und Dr. K. Müller (*Review*), 269

Lactic Dehydrogenase from Heart Muscle, Action of Co-zymase as the Specific Co-enzyme of, E. Adler, Prof. H. v. Euler and H. Hellstrom, 968
Lady Julia Percy Island, The McCoy Society's Expedition to, Prof. F. Wood Jones, 906
Lakes, Thermal Stratification in, P. Ullyott and P. Holmes, 971
Lamps, New Discharge Bulb, 836
Land-Reclamation in Italy, C. Longobardi, translated by Olivia Rossetti Agresti, Sir John Russell (*Review*), 4
Language, Truth and Logic, A. J. Ayer (*Review*), 823
Lapachol and Related Compounds, late Dr. S. C. Hooker, 1047
Lassell, William, on Casting Specula [1836], 1110
Latent Image, Evolution of the, Influence of the Wave-length of the Light on the, Mlle. Arlette Tournaire and E. Vassy, 179
Lauric Acid, Contact Potentials of Reversible Soluble Films of, R. T. Florence, R. J. Myers and Prof. W. D. Harkins, 405
Law, The, and the Prophets, H. Peake and Prof. H. J. Fleure (*Review*), 632
Lax, F.R.S., William, Death of [1836], 732
Layman's Library, The (*Review*), 862
League of Nations: Reform, 321; Rearmament and the, 1071
Leeds University: Dr. A. Durward elected professor of anatomy; donation from F. Parkinson, 46; gift by the Lord Mayor of Leeds; J. C. Gregory appointed honorary lecturer in the history of science, Dr. F. C. Happold lecturer in biochemistry, H. R. Noltie lecturer in physiology, W. Hobson part-time lecturer in physiology and hygiene and G. D. A. MacDougall assistant lecturer in economics, 215; Gift by F. Parkinson, 1067; Report of the Dept. of Pathology and Bacteriology, 1092
Leicester, Roman, a National Asset, 356; 432
Lepidoptera, Obtaining Aberrant forms of, under the influence of Chemical Reagents, J. Zacwilichowski, 897
L'Espèce, Prof. L. Cuénot (*Review*), 742
Leyden University, gift to, by the Rockefeller Foundation, 941
Liberal Arts College in State-supported Universities, Prof. H. G. Merriam, 983
Libraries: for Scientific Research in Europe and America, H. P. Spratt (*Review*), 59, Teaching the Use of, Dr. P. Hurt, 597
Lice, Sucking, Dr. G. F. Ferris, 82
Life, The Architecture of, A. D. Ritchie and others, 607
Light: and Sound, H. G. Lambert and P. E. Andrews (*Review*), 183; Scattering of, by Light, A. Akhieser, L. Landau and I. Pomeranchook, 206; Diffraction of, by Ultra-sonic Waves, F. H. Sanders, 285; Polarization of, and some Technical Applications, Prof. A. F. C. Pollard, 311; Constancy of Wave-length of, G. C. Omer, jun., 587; Diffraction of, by Ultra-Sonic Waves, Sir C. V. Raman and N. S. Nagendra Nath, 616; A. E. E. McKenzie (*Review*), 636; Velocity of, M. E. J. Gheury de Bray, 681; Diffraction of, by Ultra-sonic Waves, C. R. Extermann, 843; Neutrino Theory of, Inconsistency of the, V. Fock, 1011; Melloni's Investigations on [1836], 1068
Lighting: Public, A. Cunnington, 715; Domestic, W. J. Jones, 795
Lightning and Atmospherics, P. F. Fyson, 278; P. R. Coursey, 509
Lincoln, Potters of, 357
Linear Differential Equations, Introduction to the Theory of, E. G. C. Poole (*Review*), 629
Linkage in Man, Dr. Julia Bell and Prof. J. B. S. Haldane, 759
Linnean Society, M. A. C. Hinton elected zoological secretary, 838
Liquid at Different Temperatures, Specific Heat of a, Prof. Allan Ferguson and A. H. Cockett, 842
Liquids of High Refractive Index, B. W. Andersson and C. J. Payne, 168
Lister Institute: of Preventive Medicine, Forty-second Annual Report, 197; New Ultracentrifuge Installation at the, 654
Lithium: Alum, Preparation of, Prof J. F. Spencer and G. T. Oddie (Sister Mary Cecilia), 169; Boron and, Ranges of Particles emitted in the Disintegration of, by Slow Neutrons, J. Rotblat, 202

Liverpool: Dr. A. G. Walker appointed lecturer in pure mathematics, Dr. H. R. Hulme lecturer in applied mathematics, and Dr. C. J. Williams Leverhelme Foundation lecturer in physics, 46; and Manchester Railway, Progress on the [1836], 177; Learned Societies, 322; Biological Society, Fiftieth anniversary, 716
Locomotives, Steam, Recent Developments in, Sir H. Nigel Gresley, 793
Logic in Theory and Practice, Prof. C. G. Shaw (*Review*), 187
Logone, Zone of Capture of the, by the Bénoué, Present Condition of the, J. Tilho, 258
London: University: conferment of title of reader in neurological anatomy conferred on Miss U. L. Fielding; award of postgraduate studentships, 46; Centenary Celebrations, 84; conferment of doctorates, 176; A. Haddow re-appointed Laura de Saliceto student; W. J. E. Butler awarded the Sir George Jessel studentship in mathematics, 177; School of Economics, Dept. of Business Administration, 375; and Thames Valley, R. L. Sherlock, 389; Hospital, Research at the, 399; Meteorological Society [1836], 599; University Degrees: a Faraday Letter, 710; University: Dr. W. G. Penney appointed reader in mathematics in the Imperial College—Royal College of Science, and Dr. C. Reid reader in physiology at the London Hospital Medical College; title of professor conferred on G. I. Finch and that of emeritus professor on Prof. A. L. Bowley; Dr. S. J. Davies appointed professor of mechanical engineering at King's College, 772; conferment of doctorates on R. P. Tripathi, E. E. Jelley and R. W. Bailey, 810; School of Hygiene and Tropical Medicine, Work of the, Sir Austen Chamberlain, 877; University: conferment of doctorates on E. E. Jelley and R. W. Bailey, 895; conferment of title of professor on F. L. Golla and Dr. E. Mapother and that of reader on Dr. L. S. Bosanquet; conferment of doctorates on H. Chaudhuri, R. G. Hatton and F. C Chalklin, 940; Prof. F. A. Cavenagh appointed professor of education at King's College, 941; Telephone Trunk Exchange, H. M. Wells, 1006; and Greenwich Railway, Opening of the [1836], 1026; University, Dr. E. Giffen appointed reader in mechanical engineering at King's College; title of reader conferred on Dr. R. E. Gibbs, Dr. S. V. Keeling and Dr. D. M. Newitt and that of emeritus professor on Sir Grafton Elliot Smith, Prof. M. T. M. Ormsby, Prof. A. E. Jolliffe, Prof. W. A. Bone, Prof. A. Fowler, Prof. E. W. MacBride, Prof. S. J. Truscott and Prof. W. W. Watts, 1110
Loudon, J. C., and the Waterloo Beeches, Sir William Fraser, 277
Loudon's 'Arboretum', Centenary of, W. Roberts, 237
Loudspeakers, Appraisement of, F. H. Brittain, 1021
Louisiana, U.S.A., Mound Builders in, W. M. Walker, 805
Low: Temperature Research, Theoretical Aspects of, Prof. F. A. Lindemann, 190; Temperatures and their Industrial Uses, 190
Luminescence: of some Minerals, S. Kreutz, 733; of Solid Substances produced by Direct Excitation in a Geissler Tube, M. Servigne, 733
Luminous: Discharges observed in the Magnetic Field at Pressures below 10^{-4} mm. of Mercury, T. V. Ionescu, 90; Bacteria, Quantum Relationship of the Light-emitting Process of, K. L. van Schouwenburg and Johanna G. Eymers, 245; Phenomena on the Sea during a Thunderstorm, 278
'Lumophor' Glass for Tubes containing Luminous Gases, Glaswerk Gust. Fischer, 978
Lunettes et télescopes: théorie, conditions d'emploi, description, réglage, A. Danjon et A. Couder (*Review*), 738
Lyell: and Mantell [1836], 47; and Darwin [1836], 1110
Lyre-Bird in Victoria, F. Lewis; R. T. Littlejohns, 926
Macadam: J. L., Father of Modern Road-Making, Dr. R. Quarendon, 869, 874
McCoy Society's Expedition to Lady Julia Percy Island, The, Prof. F. Wood Jones, 906
Madder, Glycosides of, R. Hill and D. Richter, 38
Magdalenian 'Raclette' Industry, An Early, in the Lower Thames Valley, J. P. T. Burchell, 79
Magdalénien de la Grande Salle, Le, Dr. René de Saint-Périer, 1023
Magnet, Earliest Printed Book on the, 795
Magnetic: Observations in New Zealand and elsewhere, 500; Field, Oscillatory Discharges in a, 1067
Magnetron, Parallel-plane Diode, D. M. Tombs, 36
Maiden Castle, Dorchester: Excavations at, 395; Foundation Rites at, 580
Maize: Ultra-Violet Radiation in, Genetic Effects of, L. J. Stadler and G. F. Sprague, 1, 2 and 3, 1070
Maize Survey, The, R. A. Emerson and J. K. Kempton, 1090
Malaria: and Nutrition, 380, Acraquinine as a Preventive of, 1050
Malariology, Institute of, Rome, Mission to Abyssinia to Study Malaria, 1093
Malayan Zoogeography (*Review*), 622
Mall: Franklin Paine, the Story of a Mind, Florence Rena Sabin (*Review*), 663
Malta, Prehistoric Relics in, 765
Mammalian: Development, Organizers in, C. H. Waddington, 125; Fauna of the White River Oligocene. Part 1: Insectivora and Carnivora, 427
Man: The Freedom of, Prof. A. H. Compton (Terry lectures), (*Review*), 6; and Forest in Prehistoric Europe, Prof. V. G. Childe (*Review*), 95; The Progress of, 188; Makes Himself, Prof. V. Gordon Childe (*Review*), 699; The Rise of (*Review*), 699
Manatee of St. Helena, The, G. C. Kitching, 33
Manchester University: J. Jewkes elected professor of social economics, 68; resignations of Dr. T. A. Bennet-Clark, F. Morton and L. W. Derry; A. C. Lovell appointed assistant lecturer in physics, Dr. R. F. Hunter assistant lecturer in chemistry, and Dr. V. J. Chapman assistant lecturer in botany; gift of a research grant from the International Tin Research and Development Council, 772
Manchukuo, Palæolithic Site in, S. Tokunaga and N. Naora, 1019
Manganese: Trichloride, A. Chrétien and G. Varga, 334; Steel, Medallions of, 755
Manganous Sulphate, Hydrates of, E. Rencker and P. Dubois, 414
Mankind, Origins of Modern Races of, Sir Arthur Keith, 194
Manufacturing Business, Some Problems of a small, C. A. Lee, 653
Marconi-E.M.I. Television System, 514
Marine: Steam Boilers, Present Position of, Eng. Rear-Adml. W. M. Whayman, 213; Biological Association of the United Kingdom, retirement of Dr. E. J. Allen; Dr. S. Kemp appointed secretary and director of the laboratory, 235; Boring Animals injurious to Submerged Structures, Dr. W. T. Calman. Second edition, revised by G. I. Crawford, 1050
Marquesan Insects, Environment of, A. M. Adamson, 766
Marriage: in Western Civilization, The Future of, Dr. E. Westermarck (*Review*), 186; Society and the Institution of (*Review*), 186; *Hygiene*, May, 398
Martindale and Westcott, The Extra Pharmacopœia of, Twentieth edition. Vol. 2 (*Review*), 59
Mass Spectrographs, Second Order Focusing for, W. W. Sawyer, 513
Maternal Mortality and Malnutrition, Lady (Rhys) Williams, 1103
Mathematics: at Bombay, Prof. J. Maclean, 21; and Agriculture, Dr. J. Wishart (*Review*), 347; History of, The Study of the, Dr. G. Sarton (*Review*), 700; Science and, History of (*Review*), 700; for Technical Students, F. G. W. Brown. 2 Parts (*Review*), 864
Matter: Minimal Lines and Geodesics within, a Fundamental difficulty of Einstein's Theory, Dr. L. Silberstein, 1012

Maya Culture in the Highlands of Guatemala, 892
Mayflies: The Biology of, with a Systematic Account of North American species, Prof. J. G. Needham, Dr. J. R. Traver, Prof. Yin-Chi Hsu and others (*Review*), 223
Mayfly Nymphs, Oxygen Consumption of, in relation to Available Oxygen, Prof. H. Munro Fox, C. A. Wingfield and B. G. Simmonds, 1015
Meare Lake Village, Excavations at, 395
Measurement of Capacities by the Ballistic Method, Important Cause of Error in the, J. Granier, 138
Mechanical Science, Applications of, 852
Mechanics: and Hydrostatics, Dr. R. G. Mitton (*Review*), 59; Theoretical, Dynamics of Rigid Bodies, Prof. W. D. MacMillan (*Review*), 264
Medical: Statistics [1836], 137; Practitioners in the Diocese of London licensed under the Act of 3 Henry VIII, C. II; an annotated list 1529–1725, J. H. Bloom and R. Rutson James (*Review*), 142; Curriculum, The, 182; Research Council, Industrial Health Research Board of the, R. Coppock, R. K. Law and Prof. B. A. McSwiney appointed members of the, 199; Research, Post-Graduate, 360; Biography (*Review*), 663; Research Council: appointment to the, of Lord Balfour of Burleigh and Prof. J. Mellanby, 717; awards of the, to Dr. F. Murgatroyd, Dr. C. Hackett, G. B. Ludlam and J. N. Strauss, 879
Medicine: American, Dr. H. E. Sigerist. Translated by Miss H. Nagel (*Review*), 142; History of (*Review*), 142; in the Middle Ages, The Story of, Prof. D. Riesman (*Review*), 142; Talmudic, A Short History of, Dr. J. Snowman (*Review*), 142; -Man of the American Indian and his Cultural Background, The, Prof. W. T. Corlett (*Review*), 268; Forensic, Report on, 433; Pharmacy and, Contributions of Chemistry to, Dr. F. Pyman, 693
Medico-Botanical Society [1836], 854
Medieval: Painters, Formulæ of, Prof. A. P. Laurie (*Review*), 266; Painting, The Materials of, D. V. Thompson (*Review*), 266
Mediterranean: Littoral, The, A. D'Arrigo, 558; World, Unity and Diversity of the, Dr. G. Sarton, 926
Melanesian Civilization of Eastern Asia, Dr. P. V. van Stein Callenfels, 876
Melbourne University, Dr A. F. Burstall elected professor of engineering and dean of the engineering faculty in, 1003
Mendelian Ratios, Standard Errors of, S. S. Purewal and P. K. Rao, 977
Menschlichen Rassen, Die, Dr. R. Lammel (*Review*), 666
Mental: Disorders: Destiny and Disease in, with Special Reference to the Schizophrenic Psychoses, Prof. C. M. Campbell (*Review*), 386; Life, Essential Traits of, Prof. T. L. Kelley (*Review*), 952
Mercury: Arc Rectifier Practice, F. C. Orchard (*Review*), 784; Vapour, Sparking Potential of, Dr. F. Ll. Jones and W. R. Galloway, 973
Mersey Tunnel, Fire in the, 280
Mesembryanthemum, New Genus of, late Dr. N. E. Brown, 726
Mesolithic Settlement of Northern Europe: The, A Study of the Food-Gathering Peoples of Northern Europe during the Early Post-Glacial Period, Dr. J. G. D. Clark (*Review*), 95
Metabolism at High Altitudes, 935
Metallic: Zinc and Cadmium, Asymmetry in, Prof. K. Herrmann; Dr. G. W. Brindley, 290; Films, Sputtered, A New Kind of Ring Phenomenon in, Utsab Kumar Bose, 684; Films, Thin, A. C. B. Lovell, 1063
Metallurgical Text-Books (*Review*), 1032
Metallurgy: of Iron and Steel, An Introduction to the, Prof. H. M. Boylston. Second edition (*Review*), 1032; Physical: An Introduction to, Dr. L. R. Van Wert (*Review*), 1032; The Principles of, Prof. G. E. Doan (*Review*), 1032
Metallography, Principles of, Prof. R. S. Williams and Prof. V. O. Homerberg. Third edition (*Review*), 1032
Metals: and Alloys, Structure of, Dr. W. Hume-Rothery (*Review*), 7; and Brittle Materials, Fractures in, Dr. H. J. Gough and others, 132; Order of Affinity of, for Copper, Iron, Cobalt and Nickel, Dr. A. S. Russell, 161; and Alloys at High Temperatures, Specific Heats of, Prof. F. M. Jaeger; Dr. O. J. Walker, 211; Institute of, Paris Meeting of the, 691; Micrography of, in Ultra-Violet Light, J. Smiles and H. Wrighton, 855; Specific Heats of, Prof. H. L. Bronson and colleagues, 1105
Metchnikoff Institute of the Ukraine, Bulletin of, No. 1, 360
Meteor: Observations, B. S. Whitney; F. Watson, jun. and E. M. Cook; Rev. Dr. M. Davidson, 514; Trails, Photographing, S. Arend and G. C. Flammarion, 690; Heights from the Arizona Expedition, E. Öpik, 943
Meteoric Trains, Luminosity of, M. A. R. Khan, 933
Meteorites (Ærolиths) found in the Tanezrouft (Western Sahara), A. Lacroix, 984
Meteorological Office, Annual Report for year ending March 31, 1936, 1048
Meteorology: in India, 70; for Airmen in India, 108, Manual of, Sir Napier Shaw, with the assistance of Elaine Austin. Vol. 2: Comparative Meteorology. Second edition (*Review*), 781
Meteors, Orionid, J. P. M. Prentice, 978
Methane, Heavy (CH_3D) in the Photographic Infra-Red, Absorption Spectrum of, Drs. W. H. J. Childs and H. A. Jahn, 285
Metrical Space, Introduction of Directions in a, C. Pauc, 813
Meyer medal of the American Genetic Association, presentation of the, to P. H. Dorsett, 18
Mice, Male, Genital Organs of, A Protective Action of Progesterone on the, H. Burrows, 164
Microbiology, Second International Congress for, 295
Microcolorimetric Apparatus, A New, and a Method for Determination of Total Blood Volume, Dr. J. C. Somogyi, 763
Micro-fossils Included in Flints, A Means of Isolating the, Mlle. Maria Lejeune, 561
Micro-incineration Studies (3), F. M. Uber and T. H. Goodspeed, 775
Micro-organisms, Type Cultures of, 889
Microscope in Engineering and Industry, A. E. Bingham, 715
Middle-Babylonian Chemical Text, A, C. J. Gadd and R. Campbell Thompson, 555
Middlesex Hospital Medical School, The Story of the, Dr. H. Campbell Thomson (*Review*), 142
Midwives Act, Circular on the, 755
Milk: The Chemistry of, Dr. W L Davies (*Review*), 625; Graded, Bacteriological Tests for, 1050
Milks, Soured, Molecular Constant for, G. T. Pyne and Prof. J. J. Ryan, 1111
Millport, Research at, 397
Mind, The Natural History of (Tarner Lectures), A. D. Ritchie (*Review*), 618
Mineral Resources of the French Colonies (*Review*), 265
Mississippi, Exploration of the [1836], 1111
Mock Suns Observed at Nanda Devi in Garhwal, N. E. Odell, 764
Modalities: Interaction Across, Simultaneous Stimulation, C. C. Pratt, 943
Molecular: Asymmetry, Isotopes and, Dr. T. Iredale, 292; Nitrogen, Effect of, on Molybdenum at High Temperatures, P. Túry and S. Krausz, 331; Structure, Valency and, Prof. R. F. Hunter and Prof. R. Samuel, 411
Molecules: Vibrational Frequencies of, Dr. H. G. Howell, 290; and Morphogenesis, Dr. G. R. de Beer (*Review*), 863
Molekülspektren und ihre Anwendung auf chemische Probleme, Prof. H. Sponer. 1: Tabellen; Teil 2: Text (*Review*), 386
Molluscs: Land and Freshwater, of Colorado, Prof. J. Henderson, 170; and Blood Flukes, Bartsch, 371; of Northern Asia, A. Mozley, 517

Molybdenum : Effect of Molecular Nitrogen on, at High Temperatures, P. Túry and S. Krausz, 331 ; Iron and, Distortion of, Dr. E. W. Fell, 760
Mond Nickel Co., Ltd., New Laboratories of the, 771
Monogénéité, Les conditions de, Prof. D. Menchoff, 41
Montmorillonite, Generating Media of, and of Sepiolite, J. de Lapparent, 695
Montserrat, Geology of, A. G. MacGregor : Seismic Observations in, C. F. Powell, 1069
Morals, Decline and Fall of, Dr. N. Murray Butler, 559
Moravia, Archæological Excavations in, 553
Morphogenesis and the Field Concept, C. H. Waddington, 809
Moscow : Foundation in, of an Institute for Experimental Physiology and Therapeutics, 718 ; Medical Centre for, 1091
Mosquito Control and Local Authorities, 1046
Mosquitoes of the Ethiopian Region, G. H. E. Hopkins 592
Mpondo : Regimental System, A. J. H. Goodwin, 813 ; Women's Initiation among the, J. S. Griffiths, 813
Muscles, Morphology of, Prof. D. Waterston (*Review*), 221
Museums : and the Public, Sir Eric Maclagan, 172 ; Association, Annual Conference at Leeds ; Alderman C. Squire elected president, 172
Mushroom : Growing, Composts for, G. Paterson-Hart, 409 ; Beds, New Disease of, P. H. Williams, 690
Mycological Researches, J. Ramsbottom (*Review*), 1033
Mycology : Medical, Fungous Diseases of Men and other Mammals, Prof. C. W Dodge (*Review*), 185
Mycoses of Man and other Mammals, Lt.-Col. C. Crawford-Jones (*Review*), 185
Mysore Tribes and Castes, The, L. K. Ananthakrishna Iyer ; R. E. Enthoven (*Review*), 225

National : Inland Water Survey, First Annual Report, 19 ; Physical Laboratory, Annual Inspection of the, 85 ; Trust, Forty-first Annual Report, 157 ; and International Health and Welfare, 196 ; Central Library, Twelfth Annual Report, 236 ; Smoke Abatement Exhibition, H. J. Hodsman, 728 ; Museum of Wales and Welsh Cultural Studies, 751
Nation's Food Supply, Supervision of the, Dr. G. Leighton (Benjamin Ward Richardson lecture), 1006
Nations Can Live at Home, Dr. O. W. Willcox (*Review*), 58
Native : Policy in Africa, W. G. A. Ormsby-Gore, 107 ; Territories and the Union of South Africa, 155 ; Agriculture : Improvement of, in Relation to Population and Public Health, Sir A. Daniel Hall (*Review*), 305 ; in Africa and its Relationship to Population, Sir John Boyd Orr (*Review*), 305 ; School of Medicine at Suva, The, Sir James Barrett, 320
Natural : *History Magazine*, Discontinuance of the, 796
Natural History, Society for the Bibliography of, election of officers, 395 ; Resources Conservation, 680 ; Selection : Insect Coloration and, Prof. E. W. MacBride, 365 ; and Evolutionary Progress, Prof. J. S. Huxley, 451 ; 571 ; 603 ; Insect Coloration and, Prof. G. D. Hale Carpenter, 686 ; Prof. E. W. MacBride, 884 ; Science in England at the end of the Twelfth Century, Sir Stephen Gaselee, 1003 ; Selection, Prof. G. D. Hale Carpenter, 1017 ; Prof. J. B. S. Haldane ; E. B. Ford, 1053
Naval Water-Tube Boilers, Eng.-Capt. S. R. Dight, 213
Navier, Louis-Marie-Henri, death of, [1836], 337
Nebulæ : Stars and, Certain Types of, Continuous Spectra of, Dr. W. M. Cohn, 127 ; The Realm of the, Dr. E. Hubble (Mrs. Hepsa Ely Silliman memorial lectures), (*Review*), 859
Negroes and Pygmies (*Review*), 345
Neon, Argon, Helium, J. T. Randall, 191
Neoplasms, Experimental, 334
Nerves, Iron Wire and, 83
Nest Linings and Nestlings, Coloration of, Dr. Jean M. Linsdale, 470
Neuroses, Prognosis in the, An Enquiry into, Dr. T. A. Ross (*Review*), 743
Neutrino Theory of Light, Inconsistency of the, V. Fock, 1011
Neutron Absorption of Boron and Cadmium at Low Temperatures, V. Fomin, F. G. Houtermans, A. I. Leipunsky, L. B. Rusinow and L. W. Schubnikow, 505
Neutrons : Experiments with, C. H. Collie and J. H. E. Griffiths ; S. Kikuchi, H. Aoki and K. Husimi, 252 ; 'Slow', Influence of Temperature on the 'Groups' of, Dr. A. Arsenjewa-Heil, Dr. O. Heil and C. H. Westcott, 462 ; Resonance Levels for Absorption of, J. Rotblat, 545 ; and Protons, Self-Interaction of, Dr. D. Iwanenko and A. Sokolow, 684 ; Evidence for the Expulsion of Two, from Copper and Zinc by One Fast Neutron, F. A. Heyn, 723 ; Slow, Velocity of, J. R. Dunning, G. B Pegram, G. A. Mitchell, G. Fink and E. Segrè, 734 , Scattering of, by Protons, E. T. Booth and Dr. C Hurst, 1011 ; in Silver, Selective Absorption of, E. H. S. Burhop, R. D. Hill and A. A. Townsend, 1094 ; Activation of Silver by, Prof. G. Guében, 1095
Newcomen Society, Report for 1935–36, 925
New : Mexico, Early Man in, C. D. Stock and Frances D. Bode, 208 ; South Wales Soils, Phosphate Solubility in Certain, W. M. Holman, 897 ; York : City, Deaths from Motor Accidents, 718 ; York University, retirement of Prof. W. H. Park, 718 ; Zealand : New Red Alga from, N. L. Gardner, 378 ; Seismology in, Dr. C. E. Adams, 397 ; Benefits in, from Scientific Research in Agriculture, Prof. H. G. Denham, 746 ; York Zoological Society, Aquarium of the, 965
Newton, William Stukeley on (*Review*), 617
Newtoniana, Sale of, 195
Newton's : Prism in the British Museum, Prof. L. W. Taylor, 585 ; Life, Sir Isaac, Memoirs of, by William Stukeley, M.D., F.R.S., 1752, edited by A. H. White (*Review*), 617
Nickel : and Copper, Radioactive Isotopes of, Dr. C. B. Madsen, 722 ; in the Organs of Lamellibranch Molluscs, Localization of, R. Paulais, 812 ; -Iron Alloys, Magnetic Properties of the, 940
Nicotine Inhibition of Oxidation and Fermentation, Dr. G. F. Gause, 976
Night Sky : in August, 159 ; in September, 361 ; in October, 583 ; in November, 756 ; in December, 965 ; in January, 1093
Nitric Anhydride, Molecular Structure of, Raman Effect and, J. Chedin and Mme. Jeanne Cieutat Pradier, 855
Nitrogen : Fixation in Tropical Soils, Promotion of, Prof. N. R. Dhar and S. K. Mukerji, 648 ; Losses in Green Plants, Dr. W. H. Pearsall and M. C. Billimoria, 801 ; Compounds from Legume Nodules, Nature of the Excretion of, Prof. A. I. Virtanen, 880 ; in Water, Solubility of, at Ultra-Pressures up to 4,500 kgm./cm.^{2}, J. Basset and M. Dodé, 896 ; Fixation with Cow-Dung, Prof. N. R. Dhar and S. K. Mukerji, 1060
Nitroprusside Reaction as a Test for Reduced Glutathione, The, N. S. R. Maloeuf, 75
Nitrous Oxide Molecule, Cheng E. Sun and Ta-you Wu, 409
Nobel Prize : for chemistry, award of the, to Prof. P. Debye ; for physics, divided between Prof. V. F. Hess and Dr. C. D. Anderson, 873 ; for medicine divided between Sir Henry Dale and Prof. O. Loewi, 792
Nodules on Legume Roots, Physiology of the Formation of, K. V. Thimann, 775
Noise : Measurements of, B. G. Churcher and A. J. King, 329 ; on the Road, Report on, 753 ; Effect of, Dr. F. Kennedy, 935
Nomenclature, Rules of, Suggested Cases for Suspension of, Dr. C. W. Stiles, 34
Non : -Polar Molecule, Indication of a Decrease in the Polarizability of a, by Pressure, Prof. A. Michels, C. Michels-Veraart and A. Bijl, 509 ; -Aqueous Solutions, Surface Properties of, R. Aschaffenburg, 644
North : Uist, Fauna of the Brackish Water Lochs of, Edith A. T. Nicol, 178 ; African Birds and Mammals,

Biogeography and Ecology of, Dr. B. P. Uvarov, 273 ; -East Coast Institution of Engineers and Shipbuilders, awards to Eng.-Comdr. C. J. Hawkes, G. F. Hardy, R. C. Thompson, W. C. S. Wigley, A. Gilchrist and Dr. W. Pratt, 282 ; American Sunfishes, Reproductive Habits of the, C. M. Breder, 470 ; African Phosphates, Coproliths of the, L. Cayeux, 476 ; -East Land, Water under the Western Ice Cap in, R. Moss, 803 ; Sea Basin, Dr. Dudley Stamp, 1105
Northern : Lights, Prof. C. Størmer, 159 ; Plains Indians, Population of the, Dr. C. Wissler, 553 ; Transvaal, Archæological Investigations in the, Prof. C. van Riet Lowe, 580
Nova : Lacertæ : 1936, Dr. T. W. Wormell and Dr. J. C. Dobbie, 38 ; Absence of Cosmic Rays from, Dr. J. Barnóthy and Dr. M. Forró, 544 ; 1936, Peculiarities of, D. Beloritzky, 560 ; in Sagittarius, Discovery of a, C. Jackson, 681 ; in Aquila, Discovery of a, N. Tamm, 756 ; Lacertæ, Spectrum of, observed with the Large Telescope at Meudon, H. Camichel, 1112
Novæ Herculis, 1934, and Aquilæ, 1936, Spectrographic Observations of, P. Rossier, 985
Nuclear : Disintegration by a Radium B + C Source, E. F. Colbrie (2), 49 ; Levels, The Form of, Dr. P. Preiswerk and Dr. H. von Halban, jun., 163 ; Reactions Due to Neutrons of 2 m.e.v. Energy, E. T. Booth and C. Hurst, 367
Nucleo Atomico, Il, F. Rasetti (*Review*), 1037
Nucleus $^{127}_{53}$I, The Electric Quadrupole Moment of the, Dr. T. Schmidt ; Dr. S. Tolansky, 404
Number 137, The Mysterious, Sir Flinders Petrie, 81 ; C. L. T. Griffith, 332
Nursery Education, Miss I. Jones; Mrs. M. Wintringham, 731
Nutrition : The Problem of, Vol. 1, 379 ; Malaria and, 380 ; in the Colonial Empire, appointment of a committee on, 797 ; and National Health, Physique, 857 ; Some Chemical Aspects of, 1022
Nutritional : Response to Chemical Intake, Regularity of, H. C. Sherman and H. L. Campbell, 775 ; Problems, Modern, Chemical Aspects of some, Prof. J. C. Drummond (Bedson lecture), 1022
Nyasaland, Native Labour from, 835
Nyphomyiid Fly, Anatomy of a, M. Tokunaga, 806

Oak : English, Principal Rots of, Cartwright and Findlay, 409 ; Homegrown, Properties of, 471
Oat Coleoptiles, Change in the Response of, to Growth Regulators Produced by Aging, H. G. du Buy, 91
Oats : Loose Smuts of, R. McKay, 513 ; Huskless, 581
Oceania, Ancient Scandinavia and, Boat Building in, J. Hornell, 765
Oceanic Macroplankton of the *Dana* Expeditions, 45
Œnothera : *Lamarckiana*, Trisomic Mutations of, Dr. D. G. Catcheside, 690 ; Genetical and Taxonomic Investigations in, Prof. R. R. Gates, 1020
Official Statistics, Guide to Current, 1935, 360
Oil : Treatment for Uneven Blossoming, O. S. H. Reinecke, 593 ; Wells, Temperature Measurements in, M. Schlumberger, H. G. Doll and A. A. Perebinossoff, 1020
Oolitic Limestones, Study of the, by Staining and Decalcification, L. Dangeard, 49
Opalinids (Protozoa, Ciliata), Mitosis in, Tze-Tuan Chen, 1 and 2, 1070
Operophthera brumata L., Reduction Phenomena in the Morphology of the Adult Moth, A. Machotin, 657
Opium Eating and Health [1836], 942
Optics, Geometrical, Dr. H. T. Flint (*Review*), 528
Opuntia used as a Larvicide, F. G. Cawston, 179
Orang-utan, Origins of Speech and the, Prof. C. J. Connolly, 977
Orchestration, Adjustable Resonators and, Prof. W. A. Osborne, 1059
Order and Life, Dr. J. Needham (Terry lectures) (*Review*), 863
Ordnance Plans, Revision of, from Air Photographs, Col. H. L. Crosthwait, 101
Organic : Halides in Solution, Unimolecular Elimination and the Significance of the Electrical Conduction, Racemization and Halogen Replacement of Organic Halides in Solution, Dr. E. D. Hughes, Prof. C. K. Ingold and A. D. Scott, 120 ; Compounds : Reactions of, Dr. W. J. Hickinbottom (*Review*), 224 ; The Systematic Identification of, A Laboratory Manual, Prof. R. L. Shriner and Prof. R. C. Fuson (*Review*), 704
Organizers in Mammalian Development, C. H. Waddington, 125
Organometallic Compounds, Part 3, Dr. A. E. Goddard (A Text-Book of Inorganic Chemistry, edited by Dr. J. Newton Friend. Vol. 11) (*Review*), 268
Organon, No. 1, 237
Orient, The Call of the (*Review*), 1036
Orionis, Changes in the Spectrum of the Star 25, Helen Dodson, 1021
Orobanche speciosa, Germination of the Seeds of, C. Chabrolin, 414
Orthophosphoric, Sulphuric and, Acids, An X-Ray Study of, J. T. Randall, 842
Oscillatory Discharges in a Magnetic Field, 1067
Osmunda, Spiral Structure of Chromosomes in, Dr. Irene Manton, 1058
Ostrea angulata, Habit and Shell-shape in the Portuguese Oyster, Prof. J. H. Orton, 466
Oxford : Advanced Atlas, The, J. Bartholomew. Fifth edition (*Review*), 307 ; and Cambridge, Co-operation between, 678 ; University : Sir George Macdonald elected an honorary fellow of Balliol College ; Dr. W. Stephenson appointed assistant director of the Institute of Experimental Psychology, 46 ; Dr. J. H. C. Thompson elected a fellow of Wadham College and lecturer in mathematics, 89 ; Research in Social Studies in, 679 ; Dr. H. M. N. H. Irving appointed tutor in natural science at St. Edmund Hall ; A. N. Dakin elected Lady Wallis Budge fellow in Egyptology at University College ; W. G. A. Ormsby-Gore elected an honorary fellow of New College, 693 ; gifts by Lord Nuffield, 713 ; Prof. A. R. Radcliffe-Brown appointed professor of social anthropology, 751 ; Prof. A. R. Radcliffe-Brown appointed professor of social anthropology ; impending retirement of Prof. F. Soddy ; conferment of an honorary doctorate on President J. B. Conant ; scheme for the appointment of vice-chancellor ; research degrees in last academic year, 772 ; W. D. Hambly granted the degree of D.Sc. ; Dr. J. A. Douglas appointed deputy for the professor of geology, 810 ; award of the Rolleston memorial prize to J. A. Moy-Thomas and B. G. Maegraith ; award of the Theodore Williams scholarship in physiology to R. T. Campbell, 853 ; Dr. F. Simon appointed reader in thermodynamics, 874, 895 ; Dr. S. Flexner appointed George Eastman visiting professor for 1937–38 ; Prof. R. V. Southwell elected a member of the Hebdomadal Council ; Lord Nuffield elected an honorary fellow of Pembroke College ; conferment of honorary doctorates on R. W. Bingham and J. L. A. Avenol ; further gift by Lord Nuffield, 941 ; Lord Nuffield's gift to the Medical School, 1025
Oxidation : and Fermentation, Stereoisomeric Nature of, Dr. G. A. Gause, 245 ; -Reduction Potential, Prof. J. R. Partington and H. I. Stonehill ; Prof. A. A. Noyes and C. S. Garner, 252 ; Catalysis in the Living Cell, Power of, P. Joyet-Lavergne, 1027
Oxide Layer on a Polished Copper Surface, Dr. S. Dobinski, 31 ; Dr. L. H. Callendar, 291
Oxycholesterilene, Enolization of, Dr. V. A. Petrow, 645
Oxygen : Commercial Production of, C. G. Bainbridge, 191 ; In the Atmosphere, Yield of Green Plants as a Function of the Proportion of, M. Molliard, 338 ; Content of the Stratosphere, Prof. E. Regener, 544 ; Rate of Absorption of, by Sodium Sulphite Solution, W. S. E. Hickson, 645 ; Consumption of Mayfly Nymphs in relation to Available Oxygen, Prof. H. Munro Fox, C. A. Wingfield and B. G. Simmonds, 1015
Ozone as a Heating Factor in the Atmosphere, R. Penndorf, 247

Palæontology and Humanity, Prof. H. L. Hawkins, 450; 521, 534
Palæozoic Seismicity, Dr. A. Lamont, 243
Palladium: to Hydrogen, Permeability of, V. Lombard, C. Eichner and M. Albert, 48; Electronic Specific Heat in, G. L. Pickard, 123
Pancreas, The, and Blood Inorganic Phosphorus, V. Schrire and H. Zwarenstein, 180
Paradise of Fools: The, being an Account, by a Member of the Party, of the Expedition which Covered 6,300 miles of the Libyan Desert by Motor-Car in 1935, M. H. Mason (*Review*), 634
Paraffin Hydrocarbons, Normal Nitration of Some, T. Urbanski and Marion Slon, 774
Paramecium, Effect of Large Centrifugal Forces on, R. H. J. Brown, 843
Parasites, Migrating, in Ruminants, Route of, J. H. Tetley, 802
Paris: Academy of Sciences, Prof. J. Sabrazès elected a *correspondant* of the, 72; Prof. A. Maige elected a *correspondant* of the, 199; R. Esnault-Pelterie elected a member of the, 240; Academy of Medicine, Dr. P. Vallery-Radot elected a member of the, 615; University, conferment of honorary doctorates on Prof. I. Holmgren and Prof. G. D. Birkhoff, 941
Parliamentary Science Committee: additions to the, 717; election of officers, 965; The British Association a constituent member of the, with Prof. Allan Ferguson as representative, 1005
Parson in Revolt, A, Rev. J. McCulloch (*Review*), 634
Parsons: Steam Turbine, The Development of the, R. H. Parsons. 2 Parts (*Review*), 567; Sir Charles, memorial, 852; memorial lecture, Sir Frank Smith, 852
Particle Observers, Equivalent, Prof. J. L. Synge, 28
Pasteur Institute: of Southern India, Annual Report, 159; Tunis, Dr. E. Burnet nominated director of the, 615; of India, Kasauli, Annual Report, 717
Patent Actions, High Court Procedure and the Cost of, Prof. W. Cramp, 737
Patentees, Institute of, medal awards of the, 323
Patterns of Experience, The, A. W. Wolters, 670
Patwar Meteoric Shower of July 29, 1935, Dr. A. L. Coulson, 513
Paulin Aneroids, 554
Pavlov: Institute of Aviation Medicine, 681; late Prof. I. P., Documents relating to the life and work of the, 966
Pawnee: Second Oceanographic Expedition, Fishes from the, C. M. Breder, jun., 170
Pawnee Archæology, W. R. Wedel, 888
Pedology: (Soil Science) at the British Association, 729; Applied, Problems in, Dr. A. B. Stewart, 730
Peirce, Charles Sanders, Collected Papers of, edited by C. Hartshorne and P. Weiss. Vol. 6: Scientific Metaphysics (*Review*), 1037
Pelseneer, Paul, Mélanges (*Review*), 783
Peking Man: Further Discoveries, L. P. Chia, Sir Grafton Elliot Smith; Prof. F. Weidenreich, 1004; W. C. Pei, 1056
Penæids, Morphology and Distribution of, M. D. Burkenroad, 371
Pencils of Zehfuss, Singular Compound and Schlaflian Matrices, W. Ledermann, 48
Penguins, King, at Edinburgh Zoological Park, Breeding of, 878
Pennines, The, and Adjacent Areas, D. A. Wray, 390
Pentadeuterobenzoic Acid, C_6D_5COOH, Some Properties of, Prof. H. Erlenmeyer and A. Epprecht, 367
Pentane, Normal, and Oxygen, Influence of a Chemically Inert Gas on the Velocity of the Chain Reaction of Mixtures of, M. Prettre, 695
Peppermint, Cultivation and Distillation of, Leaflet on, 797
Pepsin, Crystalline, Inactivation of, Dr. J. Steinhardt, 74
Perchloric Acid: Oxidation of Some Organic Substances by, A. Vialard-Goudou, 695; Absolute, Raman Effect in, R. Fonteyne, 886
Perfumes: and Essences, Modern, H. Berry (*Review*), 949; Cosmetics and Soaps: with Especial Reference to Synthetics, W. A. Poucher. Vols. 2 and 3. Fifth edition (*Review*), 949
Periodicals, Subject Index to, 1935 (*Review*), 147
Pernambuco, The Reef at [1836], 257
Personality Maladjustments and Mental Hygiene, Dr. J. E. W. Wallin (*Review*), 636
Perthshire Tectonics; Schiehallion to Glen Lyon, Prof. E. B. Bailey and W. J. McCallien, 896
Petioles, Abscission of, Effect of Auxin on the, C. D La Rue, 91
Petroleum Fuels in Canada, 336
Petrology and Movements of Snow Deposits (*Review*), 481
Petrols of Various Sources of Origin, Proportion of Deuterium in the Light Hydrocarbons from, A. Maillard, 897
Pflanzen, hoheren, Vergleichende Morphologie der, Prof. W. Troll. Band I. Lief. 1 (*Review*), 950
Pflanzenzelle: Die, Vorlesungen uber normale und pathologische Zytomorphologie und Zytogenese, Prof. E. Kuster (*Review*), 623
Pharmaceutical Society, presentation of the Hanbury gold medal to Dr. F. Pyman, 693
Pharmacists, French, Education of [1836], 216
Pharmacological Action, Chemical and Physical Basis of, Prof A. J. Clark and others, 938
Pharmacy and Medicine, Contributions of Chemistry to, Dr. F. Pyman, 693
Phase Transitions, The Theory of, Dr. L. Landau, 840
Phenanthrene, Chemistry of Natural Products related to, Prof. L. F. Fieser (*Review*), 224
Phenol as a Function of the *p*H, Variations in the Ultra-Violet Spectrum of, Mlle. Madeleine Gex, 258
Phenylacetic Acid, Effect of, on the Growth of Tomato Plants, Dr. H. L. Pearse, 363
Pheretima (The Indian Earthworm), Prof. K. N. Bahl. Second edition (*Review*), 147; 1092
Philosophy, Guide to, C. E. M. Joad (*Review*), 100
Phloretin, Phloridzin and, Inhibitory Effect of, on Kidney Phosphatase, Dr. H. Kalckar, 289
Phosphagen in Echinoid Muscle and in Electrical Tissue, E. Baldwin and Dr. Dorothy Moyle Needham, 506
Phosphine, Heavy (PD_3), Infra-Red Absorption Spectrum of, Dr. G. B. B. M. Sutherland and G. K. T. Conn, 641
Phosphites, Constitution of Phosphorous Acid and the, R. Ananthakrishnan, 803
Phosphogluconic Acid, Fermentation of, F. Lipmann, 588
Phosphorescence, Demonstration of, H. Warren, 974
Phosphorous Acid and the Phosphites, Constitution of, R. Ananthakrishnan, 803
Phosphorus: Pentachloride, H. Moureu, M. Magat and G. Wetroff, 476; Colorimetric Estimation of, Dr. H. L. Brose and E. B. Jones, 644; A New Oxide of, P. W. Schenk and H. Platz, 849
Photo-electric Cells: for the Measurement of Energy, Standardization of, Dr. H. H. Poole and Dr. W. R. G. Atkins, 338; Effect of Hydrogen on, Dr. N. R. Campbell and R. S. Rivlin, 1063
Photographic: Plates: Sensitivity of, in the Region $\lambda\lambda$ 2500–2100 A., A. Hunter and Dr. R. W. B. Pearse, 37; Plate Action exerted by Ordinary Metals on the, and on the Electrometer, J. Reboul, 138; Plates, Variation of the Optical Density of, with the Dryness Conditions, J. Roig and J. Thouvenin, 179; Development, Theory of, A. J. Rabinovitsch and S. S. Peissachovitsch, 849; Sensitized with Sodium Salicylate, Tien Kiu, 1112
Photographs, Early, J. H. Read, 239
Photography, 81st Annual Exhibition of, International, 499
Photomicrographic Reproduction of Scientific Papers, 358
Photo: -Micrography, Practical, J. E. Barnard and F. V. Welch. Third edition (*Review*), 636; -Reduction of Fluorescent Substances by Ferrous Ions, Dr. J. Weiss, 80

Silica. Fused, The 2·73μ Absorption Band in, Dr. D. G. Drummond, 248; Colloidal, in Natural Waters and the 'Silicomolybdate' Colour Test, Dr. A. R. Tourky and Prof. D. H. Bangham, 587
Silicichloroform, Geometrical Constitution of, Prof. M. de Hemptinne and J. Wouters, 884
'Silicomolybdate' Colour Test, Colloidal Silica in Natural Waters and the, Dr. A. R. Tourky and Prof. D. H. Bangham, 587
Silicon: Organic Derivatives of, Prof. F. S. Kipping (Bakerian lecture), 41; Oxidation of, Minimum Temperature of, C. Bedel, 519; in the Plant, Role of, A. Sreenivasan, 889
Silk Fibre, Sorptive Properties of the, Dr. R. Cuthill, 175
Silkworm (*Bombyx mori* L.), Artificial Parthenogenesis in the, B. Astaurov, 656
Silver: -Gold Alloys, Quantitative Analysis of, Winifred Mannin, 260; Neutrons in, Selective Absorption of, E. H. S. Burhop, R. D. Hill and A. A. Townsend, 1094; Activation of, by Neutrons, Prof. G. Guében, 1095
Skin-Friction in Aeronautics, The Part Played by, Dr. F. W. Lanchester, 1022
Small Craft Types, J. A. Mavor, 1092
Smoke Abatement Exhibition, National, H. J. Hodsman, 728
Smuts, General, Mrs. Sarah Gertrude Millin. 2 Vols., R. Brightman (*Review*), 569
Snow Structure and Ski Fields, G. Seligman; with an Appendix on Alpine Weather, by C. K M. Douglas (*Review*), 481
$[SO_3]_2$, Prof. H. E. Armstrong, 26
Social: Reconstruction, International Economics and, 341; Life in a Rural Community, 581; Mission of Science, The, 697; Analysis, A, Sir Daniel Hall (*Review*), 779; Anthropology, Methods in, Prof. E. Westermarck (Huxley memorial lecture), 808; Change, Authority and Resistance to, Prof. J. Dewey, 915
Sociedad Cubana de Biologia, Prof. E. Abderhalden nominated an honorary member of the, 1008
Société de l'Industrie Minérale, election as honorary members of Sir Robert Hadfield, Bt., Dr. C. E. Guillaume, Prof. L. Denoel and Prof. P. Fourmarier, 18
Sodium: and Potassium Films, Transparency of, in the Schumann Region, Prof. W. H. Watson and D. G. Hurst, 124; and Water Metabolism in relation to Disturbances of Carbohydrate Metabolism after Adrenalectomy, Prof. F. Verzár and L. Laszt, 844; Chloride, Ultra-Violet Luminescence of, Prof. M. Schein and M. L. Katz, 883
Soil: Science: Prof. J. Hendrick, 457, Fertilizers and General Agronomy, Bibliography of (*Review*), 485, and Pasture Studies in the Mount Gellibrand Area, Western District of Victoria, G. W. Leeper, Ann Nicholls and S M. Wadham, 520; Profile Development, Normal Erosion as a Factor in, G. Milne, 549, Classification, Prof. G. W. Robinson, 729; Moisture in the Field, Behaviour of, Dr. R. K. Schofield, 729; Science), Pedology at the British Association, 729; Studies, Development of, Prof. J. Hendrick, 729; Humus, Direct Oxidation of, C. B. Greening, 848; Science in the Twentieth Century, Prof. J. Hendrick, 995; Drift in South Australia, 1039
Soils: Their Origin, Constitution and Classification, Prof. G. W. Robinson. Second edition (*Review*), 9
Solar: Eclipse, Total, of June 19: The Corona during the, Prof. M. Navashin, 73; Observations at Omsk, Prof. J. A. Carroll, 349; Activity and Terrestrial Phenomena, 397; System, Evolution of the, 532; Corona, Proportion of Polarized Light in the, J. Dufay and H. Grouiller, 599; Temperature, W. W. Coblentz and R. Stair, 690; Eruptions, Bright, Radio Fadings and, H. W. Newton, 1017; Rays, Rev. J. B. Reade on [1836], 1068
Solo Man, Cultural Associations of, Dr. P. van Stein Callenfels, 293
Solubility of Non-Electrolytes, Prof. J. H. Hildebrand. Second edition (*Review*), 742
'Solute', Origin of the word, Prof. J. R. Par [illegible]
Solutes in Plants, Translocation of, Dr. A. [illegible] 1099
Solutions: concentrées, Les, Prof. J. T [illegible] (*Review*), 306; Concentrated (*Review*), 306 [illegible]
Sound: Light and, H. G. Lambert and P. E. A [illegible] (*Review*), 183; Localization, Differential Sens [illegible] in, M. Upton, 415; Insulation by Doub [illegible] Parti [illegible] J. E. R. Constable, 890; Vibrations, Some [illegible] Phenomena Produced by, Prof. F. L. Hopwood, 10 [illegible]
Southampton, University College, Dr. H. S. Ruse ap [illegible] pointed professor of mathematics in, 1067
South: -Eastern Union of Scientific Societies, Annual Congress at Oxford, 88; Prof. F. E. Weiss elected president for 1937, 89; Africa, Industrial Development in, and Facilities for the Establishment of Factories. Edited by Dr. V. Bosman, 256; Australia, Wind Erosion in, F. N. Ratcliffe, 358; Africa Research Grant Board, Report for 1918–35, 542 Australia, Mining in, 582; Wales, Map of, showing th Distribution of Long Barrows and Megaliths, F. W Grimes, 613; Africa, Science in, Earl of Clarendon 713; America, Archæology of, E. J. Thompson, 716, London Entomological and Natural History Society, *Proceedings and Transactions of the*, 1935–36, 718; Sandwich Trench, Dr. N. A. Mackintosh, 726; African Marine Fishes of Commercial and Angling Importance, J. M. Marchand, 796
Soviet: Mineral Resources, The Scientific Study of, A. E. Fersman. Edited by C. P. Dutt (*Review*), 97; Arctic Stations, Prof. J. Schokalsky, 593; Medical Encyclopædia, Completion of the, 966
Space-Time, Discrete, Dr. L. Silberstein, 807
Special Libraries and Information Bureaux: Association of, Annual Conference at Oxford, 597
Species Nightmare: an Absorbing Scientific Problem, F. Chapman, 539
Specific Heats of Liquids and Gases, R. Lucas, 896
Spectrograph, Automatic Recording, for the Near Infra-red (6000–9500 A.), P. Barchewitz and A. Naherniac, 855
Spectroscope in the Observatory, Prof. R. A. Sampson, 1006
Spectroscopie appliquée, La, P. Swings (*Review*), 269
Speech, Origins of, and the Orang-utan, Prof. C. J. Connolly, 977
Spiders of Lahore, S. Dyal, 1104
Spiritual Healing, Rev. Leslie D. Weatherhead, 277
Spirogyra, Creeping Movements of, D. R. Chesterman and C. L. Foster, 403
Splashes and what they teach, Prof. Allan Ferguson, 499
Sponges of the North Sea and Baltic, Dr. W. Arndt, 333
Spontaneous Combustion [1836], 694
Spotted Wilt Virus and the Hormone Heteroauxin, Dr. B. J. Grieve, 129
Squirrel, Male Grey, Chromosomes of the, P. C. Koller, 178
Staphylococcus, Effect of Sodium Mono-iodoacetate on the Respiration of the Yellow, F. Chodat and G. Carrisson, 985
Starlight, Selective Absorption of, by Interstellar Clouds, F. H. Seares, 378
Stars: of the Spectral Types *A*0, *A*2, Colour of, V. Maitre, 90; and Nebulæ, certain types of, Continuous Spectra of, Dr. W. M. Cohn, 127; *B*-type, Spectra of, E. G. Williams, 334; and Telescopes, J. Stokley (*Review*), 821; Effective Temperature of, Approximate Expression of the Colour Index as a Linear Function of the Inverse of the, P. Rossier, 985
Statistical: Research Memoirs. Vol. 1, 252; Desiderata [1836], 257
Statistics: Application of, to Commerce [1836], 773; Consumption of, Lord Kennet, 876
Steam Locomotive Design, D. Patrick, 1092
Steamship Communication between Europe and America, H. G. Leivesley, 925
Stearin from Chilled Olive Oil, Inhibited Deposition of, Dr. W. Clayton, S. Back, R. I. Johnson and J. F. Morse, 801

TITLE INDEX

with Hot Hydrogen under Pressure,
al Properties of, L. Jacqué, 985
r, Electrically Driven, H. G. Leivesley, 555
mospheres, Speed of Corpuscles ejected from,
agihara, 301; Proper Motions, Catalogue of,
R. Schorr, 767; Atmospheres, Dissociation
ergy of Carbon Monoxide and the Abundance of
lements in, M. Nicolet, 1097
kfontein Ape, The, Dr. E. Schwarz, 969
eochemical Investigations, Use of Deuterium as an Indicator in, Prof. H. Erlenmeyer, H. Schenkel and A. Epprecht, 547
Stereoscopic Photography: its Application to Science, Industry and Education, A. W. Judge. Second edition (*Review*), 637
Stick: Insect, The Common, Sister Carmela Hayes, 886; Insects, Feeding Habits of, S. T. E. Dark, 1058
tocks, New Disease of, W. M. Ware, 766
oebe, The genus, Mrs. M. R. Levyns, 217
ork Experiments, Anglo-German, 108
tratosphere: Oxygen Content of the, Prof. E. Regener, 544; Flight, 676; The Chemical Exploration of the, Prof. F. A. Paneth, 834
Straw, Two Ends of, Dr. H. Nicol, 398
Streamlined Trains, L. K. Sillcox, 238
Streptococcus apis, Relation of so-called, to certain Lactic Acid Streptococci, Dr. J. G. Davis and Dr. H. L. A. Tarr, 763
Structure: -Factor Graphs for Crystal Analysis, Prof. W. L. Bragg, 362; Determination, A Reagent for, R. Connor and J. H. Van Campen, 372; Factor and Electron Density Formulæ, Dr. J. M. Robertson (*Review*), 627; Simplified, and Electron Density Formulæ for the 230 Space Groups of Mathematical Crystallography, Dr. Kathleen Lonsdale (*Review*), 627
Structures: in Sea Water, Deterioration of, Dr. B. Cunningham, 148; of Timber, Metal and Concrete exposed to the Action of Sea-Water, Deterioration of, Fifteenth Report. Edited by S. M. Dixon and H. J. Grose, 148
Sturgeon's *Annals of Electricity*, 559
Sudamerikas, Geologie, Prof. H. Gerth. Teil 2 (*Review*), 147
Sugars: Maple and Cane, Lead Values in, P. Riou and J. Delorme, 138; from the Intestine of Rat and Pigeon, Relative Velocities of the Absorption of Different, Dr. H. G. K. Westenbrink, 203
Suicide: Scientific Study of, 583; at Aberdeen, Statistics of [1836], 773
Sulfuric Acid Manufacture, A. M. Fairlie (*Review*), 568
Sulphuric and Orthophosphoric Acids, An X-Ray study of, J. T. Randall, 842
Sumerian Art History, Racial Elements in, Sir Leonard Woolley, 69
Sun: Eclipse of the, of June 19, 1936, E. Esclangon, 216; Eclipses of the, Prof. S A. Mitchell. Fourth edition (*Review*), 823
Sundabogens: Die Geschichte des, eine tiergeographische Untersuchung, Dr. B. Rensch (*Review*), 622
Sunspot, A Large, 399
Sunspots, Three Large, 965
Super-novæ, Physical Condition of the, Cecilia Payne Gaposchkin, 378
Supraconductivity: Destruction of, by Electric Current and Magnetic Field, L. W. Shubnikov, 545; Transition Curve for the Destruction of, by an Electric Current, L. W. Shubnikov and N. E. Alexejevski, 804
Supraconductors, Time Effects in, K. Mendelssohn and R. B. Pontius, 29
Surface Forces, Range of Action of, Dr. B. Derjaguin, 330; Dr. J. M. Macaulay, 587
Suspended Animation [1836], 215
Sussex, Fauna of, N. F. Ticehurst and others, 592
Swallows in Britain, A. W. Boyd, 553
Swedish Academy of Sciences, Prof. C. Neuberg elected a foreign member of the, 502
Swinton, Campbell, and Television, Dr. J. D. McGee, 674
Switchgear, Testing, 877
Switzerland, Teaching Electric Cookery in, 754
Symbols for Heat and Thermodynamics, 281
Syndrome produced by Diverse Nocuous Agents, A, Prof. H. Selye, 32
Syria: and Crete: Further Discoveries, Sir Leonard Woolley, 20; Archæological Investigations in, Sir Leonard Woolley, 235; Ancient, Minoan influences in, Sir Arthur Evans, 357
Systematists and Text-Books, Dr. L. D. Brongersma, 280

Tables annuelles de constantes et données numériques de chimie, physique, biologie et technologie, Dr. M. Magat. Années: 1931 à 1934 (*Review*), 743
Teak Squares, Grading of, L. N. Seaman and V. D. Limaye, 1007
Technical College Equipment, 433
Telegraph Services, British, Developments in, L. H. Harris, E. H. Jolley and F. D. Morrell, 893
Telephone Development in Birmingham, 541
Telescopes: Astronomical, Dr. H. Spencer Jones (*Review*), 739; Stars and, J. Stokley (*Review*), 821; Through the, a Story of the Stars, Prof. E. A. Fath (*Review*), 821
Televiewers, All manner of (*Review*), 421
Television: in the Home, 394; M. G. Scroggie (*Review*), 421; Popular, H. J. B. Chapple (*Review*), 421; Reception, Baron M. von Ardenne. Translated by O. S. Puckle (*Review*), 421; Demonstrations in London, 615; Campbell Swinton and, Dr. J. D. McGee, 674; Service, B.B.C., Opening of, 793; in the London Area, 962
Tell Duweir, Palestine, Excavations at, 1935–36, 135
Temminckia: a Journal of Systematic Zoology. Edited by Prof. H. Boschma. Vol. 1 (*Review*), 98
Temperature Scale, The, Prof. Keesom and Dr. W. Tuyn, 977
Temperatures: below 1° K., Dr. F. Simon, 190; Low, and their Industrial Uses, 190
Températures, Mesure des, Prof. G. Ribaud (*Review*), 905
Terminology in Physics, Prof. C G. Darwin, 908
Terms used in Nutrition, Plea for Scientific Definition of, Sir Josiah Stamp, 746
Terrestrial Magnetism in Chile [1836], 216
Tertiary Igneous Rocks (Antrim and Staffa), New Analyses of, Prof. A. Holmes, 300
Tetranitromethane, Constitution of, Prof. C. Krauz and Dr. J. M. Štěpanek, 807; Prof. R. Robinson, 975
Tetraploidy and Hymenoptera, F. Greenshields, 330
Textile Institute, Journal of the, W. J. Hall appointed technical editor of the, 543
Thermal Neutrons in Silver at Low Temperatures, Absorption of, V. Fomin, F. G. Houtermans, I. W. Kurtschatov, A. I. Leipunski, L. Shubnikov and G. Shtshepkin, 326
Thiochrome, Aneurin and, The Structure of, F. Bergel and A. R. Todd, 76; 119; 406
Thiocyanogen, Sulphide, Selenide and Thioselenide of, A. Baroni, 340
Thiophosphoryl Chloride, Raman Spectrum of, Prof. V. N. Thatte, 468
Thorium: Uranium and, Atomic Masses of, Prof. A. J. Dempster, 120; Artificial Radioactivity of, Elisabeth Rona and Elisabeth Neuninger, 657
Threads, Rotating, Stability of, H. W. Hall, 932
Thulium, Artificial Radioactivity of, Elisabeth Rona and Elisabeth Neuninger, 657
Thunderstorms: British, E. G. Bilham, 851; Continuing Summer Thunderstorms. Fourth Annual Report, 1934, S. M. Bower and others, Vol. 2, Part 1, 851
Thyratrons, Changing Direct Current to Alternating Current by means of, A. W. Hull, 415
Thyroglobulin, Association and Dissociation Reactions of, Dr. H. P. Lundgren, 122
Tibet, Plant Hunting and Exploration in, Capt. F. Kingdon-Ward, 516
Tibetan Blood Groups, Prof. R. R. Gates, 293
Tierreich, Das, Lief. 65, Bearbeitet von F. Bryk (*Review*), 146

Tiere Deutschlands, Biologie der, Herausgegeben von Prof. P. Schulze. Lief. 37. Teil 26: Orthopteroidea II, Phasmodea, Saltatoria. Von M. Beier. Lief. 38. Teil 9: Acanthocephala, Kratzer, von F. Bock; Teil 31: Hemiptera III, von H. Weber (*Review*), 528
Timbers, Structural, Strength Tests of, C. J. Chaplin and E. H. Nevard, 129
Tissue: Cells, Electrolytes and a General Phenomenon in, Prof. H. Grossfeld, 31; Normal and Tumour, Comparative Effects of X-Rays and Neutrons on, J. H. Lawrence P. C. Aebersold and E. O. Lawrence, 943
Tissues, Analysis of, for Metallic Content, H. Ramage, 762
Titanium Salts, Electrolysis of Solutions of, Mme. H. Emmanuel-Zavizziano and M. Haissinsky, 414
Toad, Common, Spawning of the, G. Shrubsole, 835
Tobacco: Mosaic Virus, Inhibitors of, Dr. J. Caldwell, 83; Downy Mildew of, Control of, Dr. H. R. Angell, J. M. Allan and A. V. Hill, 334
Tomato Plants, Effect of Phenylacetic Acid on the Growth of, Dr. H. L. Pearse, 363
Tonal Brightness, Nature of, E. G. Boring and S. S. Stevens, 775
Topics of the Age for Everyman (*Review*), 901
Toronto University, Dr. D. D. van Slyke awarded the Charles Mickle fellowship, 282
Total Solar Eclipse, Auroral Phenomena and the Behaviour of the Ionosphere during a, Prof. L. Vegard, 974
Trajectories in Calibrations, Errors produced by the Inclination of the, carried out by means of Hydrometric Screws with Counting Gear, L. Escande and G. Sabathe, 984
Trans-Atlantic Steam Navigation [1836], 47
Transformer Testing, Impulse Voltages for, Dr. T. E. Allibone, D. B. McKenzie and F. R. Perry, 937
Transport: Development of, Sir Alexander Gibb, 794; Land, Sir Philip Dawson, 892
Travancore, Temples and Castes in, Maharajah of Travancore, 875
Tree: -Ring Chronology in American Prehistory, 315; Stem of a, Convection of Heat and Materials in the, Prof. H. H. Dixon, 1111
Trees: Old, Care of, A. D. C. Le Sueur, 109; and Shrubs Hardy in the British Isles, W. J. Bean. Vol. 3 (*Review*), 346; and Shrubs, New Ornamental (*Review*), 346; and Shrubs, The Identification of, F. K. Makins (*Review*), 348; Pacific Coast, An Illustrated Manual of, Prof. H. E. McMinn and Evelyn Maino, with list of trees recommended for various uses on the Pacific Coast, Prof. H. W. Shepherd (*Review*), 570
Tridacna and its Relatives, Biology of, 473
Tridacnidæ, Mode of Life, Feeding, Digestion and Symbiosis with Zooxanthellæ in the, Prof. C. M. Yonge, 473
Triodes, with Large Diameter Plate in very High Frequencies, Properties of, E. Pierret, 339
Tripolje Settlement in Kiev Province, 1103
Triterpene Group, A Novel Interrelationship in the, J. H. Beynon, Prof. I. M. Heilbron and Dr. F. S. Spring, 1017
Trout Heresy, P. B. M. Allan (*Review*), 308
Tube Trains, New, in London, 925
Tuberculosis: Prevention of, 158; and Inheritance, Prof. R. Pearl, 333; and Cattle, 717
Turbines, Multi-Cylinder Steam, J. T. Moore, 849
Turf Nurseries, Sir John Stirling Maxwell, 298
Turkey, Modern, The Making of, from Byzantium to Angora, Sir Harry Luke (*Review*), 743
Typhoid Bacilli from Water, Isolation of, A. Charlotte Ruys, 259
Typhoons and Indian weather, V. D. Iyer, 936

Ukraine, Professional Workers in the, 927
Ultra: -Violet, Extreme, Measurements of Double Refraction in the, R. Servant, 48; -Sonic Waves, Diffraction of Light by, F. H. Sanders, 286; Kurzen Wellen, Physik und Technik der, Dr. H. E. Hollman. Band 1 (*Review*), 822; -Short Waves, High-Frequency Modulation of, S. S. Banerjee and B. N. Singh, 890; -Sonic Vibrations, Effects Produced by, Dr. L. A. Chambers, 1091
Unimolecular Elimination and the Significanc Electrical Conduction, Racemization and Replacement of Organic Halides in Solut E. D. Hughes, Prof. C. K. Ingold and A. D. Sc
Universities: Research and Teaching in, 303; R in, Dr. R. Coulborn, 304; Research and Teachi Prof. R. A. Peters, 590; of the British Empire, Quinquennial Congress, 1108
University: Institutions in Great Britain and Irelan Faculties available in, for Students from Abroad, 177; Education, Purposes of, 219; Function of a, Prof. L. Cazamian, 303; Value of a, Sir James Barrett, 303; Series: The Highlights of Modern Knowledge. The Coming and Evolution of Life, Prof. H. E. Crampton; Heredity and Variation, Prof. L. C. Dunn; The Coming of Man, Dr. G. G. MacCurdy; The Races of Man, Prof. R. B. Bean; The Animal World, Prof. J. G. Needham; The Smallest Living Things, Prof. G. N. Calkins; The Earth, Dr. C. A. Reeds; Fossils, Prof. R. S. Lull; The Plant World, Dr. C S. Gager; Energy and Matter, Prof. C. B. Bazzoni; Space, Time, and Relativity, Prof. H H. Sheldon; Stars and Planets, Prof. D. H. Menzel (*Review*), 862
Upper: Elastic Limit, Importance of the, F. Rinagl, 218; Palæozoic Rocks around Yessabah near Kempsey, N.S.W., A. H. Voisey, 259; Palæolithic, Cultures of the, Miss D. A. E. No. 3479 SATURDAY, JULY 4, 1936 Vol. 138

Religion—a Changing Force?

IT will always be a paradox that the gentlest and most lovable character in the whole of the recorded history of mankind should not only be the source of such bitterness and hatred as mark the story of Christianity, but also that He Himself should have been fully aware that the consequences of His teaching would constantly be averse from the spirit of His doctrine. Of all the utterances of Our Lord, that which displays most clearly His insight into the heart of man, and has been most completely fulfilled, is the declaration that he brought into the world not peace, but a sword. Not only did He knowingly set up insurmountable barriers between those who followed Him and their families, friends and fellows in the community, but also when He turned from the Jews to send the seventy disciples on their mission to the world, He informed His religion with an inflexible will to the conversion of the heathen—in other words, of those not of like belief—which in its methods and its results has belied the promise to mankind of peace and goodwill.

Too often in its history, the missioner of Christianity has been of the type of the inquisitor and the conquistador; the fate of its converts a degradation and an extinction no less complete in its results, if less drastic in its methods, than the fate which overtook so many of the Indians of Mexico and Peru. Not indeed that Christianity here stands alone. The first great tragedy of Calvary was a prelude to the beasts of Ephesus, the spectacular slaughters, the crucifixions and the pyres of Rome. If that tragedy was re-enacted time and again in the sectarian quarrels of European civilization through the ages, elsewhere, to name one instance only, the Moslem world enlarged the circle of the Faithful by the persuasion of fire and sword.

A post-War generation, weary of strife, in its desire to build "a brave new world", would have consigned all such antagonisms to the limbo of errors and absurdities of an outworn dispensation. Frank and open discussion of differences, and co-operation, despite these differences, of all of good-will in the promotion of common aims, were to take the place of sectional rivalries and obstructions. Leagues of intellectual co-operation, and international conferences and congresses sprang up on all sides to discuss and deal with every kind of problem which stood in the way of the advancement of mankind—moral, intellectual and social. The events of more recent years have brought a bitter disillusionment to those who thought that Armageddon had passed and the millennium was due to arrive.

The present, however, is no time for pessimism; and least of all does it befit science either to belittle what has been effected by co-operative effort since the War—and the sum total is by no means negligible as the record of the non-political activities of the League of Nations can show—or to despair of the endeavour which is being made to keep open some of the ways to interchange of thought and mutual assistance, at a time when differences of outlook and tradition are being emphasized and barriers of mistrust are being re-erected. There are still matters of universal significance for mankind in which the co-operation of all may be invited, if indeed it be not essential.

Yet, however strong the conviction that a sturdy, and at times dogged, optimism is the only creed for the man of science, as well as a necessary condition of constant progress in the understanding of Nature and the universe, there are whole departments of thought, with their corollaries in human conduct and affairs, from which the principle of universality, which is a condition of world-wide co-operation, seems to be excluded. Co-operation rests, ultimately, on a truth which, in a scientific sense, is universal—in fact, a 'law'. This is the ultimate principle, whether in dealing with the suppression of the drug traffic or with 'sanctions'. But in the field of religious beliefs, on a detached view, truth is relative to the object of belief, and departmental. The code of thought, and its materialization in action, which befits the Buddhist, cannot be reconciled with that of the Christian, however near their approach.

More than passing interest, therefore, will be aroused in many not directly concerned, and irrespective of religious belief, by the announcement that during the early half of the month of July representatives of the more important religions of the world are gathering in London at a World Congress of Faiths for the discussion of "World Fellowship" as a way to the solution of world problems—the problems of war and of social and economic difficulties, which seem inevitably to lead to disaster. Neither the validity nor the possibility of fusion of the religions represented will be under consideration; but each religion is invited to consider how, maintaining its individuality, it can best contribute to the common end.

The organization of the Congress, which opened on July 3, fully maintains the claim that it is both international and inter-religious. The international president is H.H. the Maharaja Gaekwar of Baroda, and the chairman of the British National Council is Sir Francis Younghusband. The chairmen, speakers and openers of debate at sessional meetings have been selected with strict impartiality for their ability to further discussion, without preference of creed. For the attainment of what may be taken to be the more general purpose of the Congress, the dissemination over the widest possible field of a knowledge of the varied lines of approach to the major problems of existence among different peoples and creeds, the greatest importance must be attached to the series of public meetings at which distinguished members of the Christian, Jewish, Buddhist, Hindu and Moslem religions, as well as of independent thought, will expound their respective conceptions of "The Supreme Spiritual Ideal".

To bring together representatives of these different faiths, some of which, it might be thought, would mix as readily as oil and water, for the discussion of such a topic as "world-fellowship" is in itself no mean accomplishment. It does at least lend some colour to the expectation of a not entirely unfavourable answer to the inevitable question, whether any practical outcome is to be anticipated from this attempt to secure co-operation among the more liberal spirits of the various religious beliefs in the solution of world problems.

In view of the past history of religious animosities, the whole project may seem Utopian, the forlorn hope of enthusiasm. Has the time really come when the lion will lie down with the lamb? Have these religious differences been composed, and is the *odium theologicum* a thing of the past? Perhaps we may construe current events as a turn in the tide. In the Education Bill which has now passed through Parliament, for example, we seem to be entering upon the final phase in a settlement of a denominational religious difference which has been an obstacle to progress in popular education for well over a hundred years, and a source of social disintegration for three times that period. The Church of England, it is true, failed to reach a satisfactory conclusion in its overtures to the Orthodox Church; but in other directions, as for example, recently in Finland, it has been more successful. Do these movements and others of a like character point to a weakening of the religious fibre, manifested in a lessening of the spirit of aggression, or do they represent a further stage in progress towards a higher development of religious activity?

To attempt an answer would involve a combination of prophecy and analysis which would be neither profitable nor appropriate here. This much, however, may be said. Religion as a social phenomenon, and not as an individual experience, as the student of religions well knows, is a sublimation of group solidarity. In a supreme self-protective effort it either proselytizes, expels, or exterminates: hence missionary effort and persecution, on the principle that he who is not for is against. This lies at the root of the quarrel of Nazi nationalism, a quasi-religious emotion, and the Confessionals in Germany, just as it inspires the persecution of the Jews. The Old Testament expresses it repeatedly in the reliance of the Hebrews on Jehovah, the god of battles, as the exclusive protector of the Chosen People.

To some extent at the present time this particularist spirit of self-protection has been diverted into the channel of nationalism. More potent, however, is the fact that an ever-increasing number, appealing in the conditions of modern civilization to a widening circle, is not content to rest in the particular, but must pass on to the universal. To such, neither restrictions of national distinction nor differences between creeds can weigh in the balance against the ethical principles explicit or implied in all the higher forms of religion. In this composite but practical creed, analogous to the *jus gentium* of the legists, it may be that they are feeling their way towards a further and higher stage in the development of religious belief, in which the theological differences which antagonize will be forgotten in the pursuit of a common and universal ethical purpose.

Colonial Policy and Scientific Research

MR. ORMSBY-GORE has lost no time on taking up his duties as Secretary of State for the Colonies, in making clear his personal position in relation to a variety of problems with which he is confronted in colonial administration, and more particularly to the need for the active prosecution of research with a view to future development.

An address which he delivered recently, when presiding at the thirty-fifth annual Colonial Service dinner of the Corona Club, was broadcast, and was no doubt consciously directed to reach a wider public than his immediate audience. It will go far to allay some not unjustifiable feelings of uneasiness as to future developments, which for some time have disturbed informed opinion both at home and in the Dependencies. While Mr. Ormsby-Gore deprecated the discussions, in which the possibility of future sessions of territory had been debated, as likely to do more harm than good, he was emphatic in endorsing "the very clear statements" of the Prime Minister and of his predecessor in office, referring specifically among other dependencies to Tanganyika Territory. "Peace," he went on to say, "continuity of policy, social progress, and economic development are the greatest needs of the Colonial Empire."

With this all will agree, although there may be difference of opinion as to the best means by which they are to be attained. It is significant, however, of the confidence inspired by Mr. Ormsby-Gore's appointment, that it has made optimistic even so sturdy a champion of the white settlers' claims in Kenya as Lord Frederick Scott, who, as he told the East African group of the Overseas League on June 18, sees hope for the future in the appointment of "a new Secretary of State for the Colonies, who knew East Africa, and had written . . . the best of all reports on East Africa".

While Mr. Ormsby-Gore is fully alive to the part which has been played, and must continue to be played, by the study of native institutions in their bearing on the further development of the native, there are two matters to which he directed attention as problems of public health confronting the Colonial Governments. Of these the first is the application of the newer scientific knowledge of nutrition. Mental and physical efficiency, as well as resistance to disease, he pointed out, are tremendously affected by nutrition; and he is not satisfied that the problems of nutrition have been adequately studied and the results applied in our tropical dependencies. After a reference to the generous offer of the Rockefeller Foundation to establish a special organisation in Uganda for the study of yellow fever, he spoke of the benefactions received by many Colonies from the Carnegie Corporation of New York, particularly in connexion with education, social services and libraries.

It is especially satisfactory to hear that Mr. Ormsby-Gore intends to devote his personal attention to the application of science to Colonial problems of agricultural development and public health, and to watch with a vigilant eye the work of the education departments throughout the Colonies. In this connexion it may not be inopportune to note that Lord Linlithgow, Viceroy of India, in addressing the opening meeting of the Advisory Committee of Nutrition under the Indian Research Fund Association at Simla on June 18, referred to the relationship of improvement in sanitation, hygiene and nutrition among the rural population to literacy among the women: "In default of female literacy," he said, "it will be found that, whenever supervision is removed, there will be a relapse into age-old customs, and that within a few months nothing will be left of the better living that has been so laboriously inculcated." The experience of India in the past ten years may not be without its lessons for the colonial administrator.

Land-Reclamation in Italy

Land-Reclamation in Italy:
Rural Revival in the Building of a Nation. By Cesare Longobardi. Translated from the Italian by Olivia Rossetti Agresti. Pp. xii+243+29 plates. (London: P. S. King and Son, Ltd., 1936.) 12*s*. 6*d*. net.

ONE of the achievements of which Fascism can unreservedly be proud is the reclamation of great areas of land in Italy that for centuries had added little or nothing to the national wealth, and indeed had frequently, like the Pontine Marshes, been dangerous to human beings owing to the widespread prevalence of malaria. Waste land can be found in all countries, even in our own, densely populated as it is; it escaped enclosure in the old days because it could not be cultivated by the methods then in use. Considerable areas are, however, amenable to modern methods of cultivation, though the cost of reclamation might be too high to permit an economical return on the money expended. For this reason land-reclamation is scarcely proceeding at all in England, though occasionally private individuals embark on the enterprise out of sheer love of the work. In Holland the great Zuyder Zee scheme is being financed by the Government, but it is regarded not as a financial but as a social investment, to provide land on to which the growing population may spread. In the western European countries the problem is complicated by the many private rights which, though long in abeyance, may burst into vitality as soon as there is any suggestion of the land being developed or taken over for public purposes. In countries ruled by a dictator as in Italy and Russia, such questions do not arise, and land-reclamation becomes simply a technical problem which can be carried out regardless of cost.

One of the greatest of the Italian schemes was described by Dr. Roberto Almagia in NATURE of June 15, 1935. There he shows how the great Pontine Marshes have been converted from malarial swamps into good farming land. The present writer visited this region in April 1934 and was greatly impressed with the efficiency of the work and the adequacy of the houses and farm buildings. Hitherto it has been difficult for English experts to obtain information on the many administrative and financial problems involved. These are satisfactorily dealt with by Señor Cesare Longobardi, so that we now have a full account of the procedure and some statement of the cost of the work.

Reclamation has progressed rapidly since the Fascists came into power. In their first years of office, some 5,000,000 man days were given to this work; in 1933–34, their twelfth year of office, this had increased to nearly 18,000,000 man days. Some 4·7 million hectares are already in hand or completed, and marked increases in output of agricultural produce have already been obtained. The production of wheat, which before the War was less than 5,000,000 metric tons per annum, has risen to nearly 7,000,000 tons; net imports of wheat, formerly 1·4 million tons per annum, fell in 1934 to 235,700 tons only.

The Italian reclamation schemes extend also to the land which, though cultivated, is not properly utilized, especially to the well-known latifundia, agricultural properties on which farming is extremely primitive and extensive, where the farms form "a compact mass untraversed by roads, with no water system, infested by malaria, with hardly any permanent inhabitants". The latifundia are associated with what is known as the 'Southern Question', the group of problems arising out of the backward economic and social development of the south of Italy and the islands as compared with other parts of the country.

The general machinery for the reclamation is prescribed by the Mussolini Act which characteristically, as the author states, "does not lose itself in the maze of existing measures It leaves them as they are and goes straight forward". It makes financial provision over a period of fourteen years for work amounting to 7,000,000,000 lire; it directs special attention to works nearing completion; and it opens the way for further developments which experience may suggest. Of the 7,000,000,000 lire, 4,300,000,000 was to be chargeable to the Treasury and the remainder to the land owners. The major part of the finance is provided in the form of 30-year annuities discounted to the parties concerned by several different institutions. The whole of the money has already been taken up, but there still remains much work to be done.

The author states that the Act was received with great enthusiasm by the whole country. The projects submitted would have cost in the aggregate ten or fifteen times the amount available, and therefore rigid selection had to be exercised. The rights of the owners were in principal acknowledged, and, where curtailed, were said to be adequately but not excessively compensated. Preference was given for the execution of the work by consortia of landowners or public bodies, which appear to be something like the public utility societies of Great Britain. This method avoided the danger of supplanting private initiative by State intervention; at the same time it prevented the work from stopping directly the Government had fulfilled its part of the contract and before the landowners had completed theirs. The procedure is dealt with at considerable length. A special section of the Ministry of Agriculture deals with land-reclamation, and receives proposals or itself draws up plans. No project is accepted unless it shows considerable possibility of securing notable improvements in hygiene, demographic, economic and social conditions.

The plan being accepted by the Government, the landowners proceed to execute the works either themselves or through the consortium. They may provide all the money themselves or obtain Government grants or special loans from the agricultural banks. The arrangements seem to be very elastic. A very active body, however, is the National League of Ex-Service Men (Opera Nazionale per i Combattenti), whose name one sees painted up on the buildings in many of these reclaimed areas. The League has special privileges, and can demand the expropriation of landowners even if they are ready to reclaim the land. Whatever is reclaimed by the League is used for small holdings on which ex-Service men or their families are settled. Mussolini attaches great importance to this body as being, in his own words, "mobilised to perform a task with the urgency of which I am more than ever impressed, that of ruralising Italy". When the reclamation is completed, some internal migration and land settlement become necessary; a special commissariat exists to organise this. The migrants are mainly farm workers brought from more densely settled regions; in 1933, for example, some 15,000 farm workers were moved but only 500 industrial workers.

Economic law, however, still seems to operate to some extent in Italy, for we are told that the serious fall in prices of farm products after 1929 made it impossible for the landowners in some years to meet their share of the cost, and consequently Government help had to be given. The portion of the costs chargeable to the landowners is divided between them in proportion to the advantage accruing to each as a result of the work. It is impossible to ascertain this precisely beforehand, hence a provisional apportionment is made and adjusted when reclamation is completed. The credit is held against each landowner by the consortium in the form of 30-year annuities, which rank as a charge on the land immediately after the land tax and the provincial and municipal surtaxes. As the landowners themselves were unable to pay the necessary money, various banks were established for the purpose of enabling them to do so.

Considerable details are given in regard to the larger schemes. The great Pontine Marsh is cut up into holdings of 25–75 acres according to the quality of the land, each furnished with a house, stabling for ten cattle, poultry run, pig sty, well, etc. The Ex-Service Men's League has obtained grants for the settlement of some 100,000 acres. Families are brought by the Commissariat for Internal Migrations; as they have no capital, the farms are taken from the League on a crop-sharing plan, the tenants receiving monthly advances in the shape of supplies and cash allowances from the League, which directs the management of the farm. When the head of the family has acquired the necessary experience and has returned the advances made by the League, an agreement is to be drawn up under which he will purchase the farm and the livestock from the League in fifteen annual instalments covering capital and interest at the official bank rate. The farms are grouped in batches of 130, around one of the three new towns, Littoria, Sabaudia and Pontinia. An expert adviser is available. The cost of the scheme is estimated at 7,000–25,000 lire per hectare; the purchase money therefore amounts to annual payments for fifteen years of sums varying from 200 to 630 lire per hectare, in addition to an annual payment of 70 lire per hectare as cost of upkeep and amortisation of the drainage works. These repayments, however, do not cover the Government contribution, but only that made by the concessionaires. No mention is made as to how the Government share is to be recouped. There is a similar, but somewhat smaller, reclamation scheme in the lower Piave region running towards the Adriatic, and others on the Brisighella in the Lower Apennines, the Sele Plain, the Tirso, etc. The book ends appropriately with some long extracts from Mussolini's speeches on various important occasions in connexion with reclamations.

Señor Longobardi's book gives the best account at present available of Mussolini's remarkable achievements in land-reclamation. They are a challenge to other countries, and in reading about them, and still more in going over them, one is repeatedly asking whether such rapid improvements would be possible under the milder methods of western Europe. E. J. RUSSELL.

Determinism and Man

The Freedom of Man

By Arthur H. Compton. (The Terry Lectures.) Pp. xii + 153. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1935.) 9*s*. net.

SCIENTIFIC writers who have turned to the philosophical interpretation of science are invariably concerned with the relation between man and the physical and biological science he creates. These writers fall, roughly speaking, into three schools.

The first maintains that the methods that man has evolved for the study of the physical universe can be applied, without fundamental modification, to the study of mankind, and of man as an individual; that the determinism of physical science must apply equally to characteristics of the individual, and that from this can be deduced the behaviour of the mass. The universe, including man, is a complex machine. These are mechanists.

The second school sets man and his mind apart from the rest of the universe, asserts that although he is amenable to physical laws, these do not determine the whole of his actions, and that otherwise he is 'free' to act as he wills, in accordance with or against his moral conscience. There is a great variety of such philosophical idealists, ranging from the solipsist who maintains that the universe is created out of the elements of his (the particular solipsist's) consciousness, to those who believe that man, in the exercise of his will, is working out the law of a Superior Intelligence that exists outside man.

The third class asserts that man is a product of material nature, consciousness being a complex quality of the brain; that physical science has been produced by man in his struggle with the material world; that the scientific laws he finds operative to inanimate matter are not necessarily valid as they stand for the more complex problem arising when man, the active agent, is involved, the wider problem of 'man performing the social activity science', for example; but that this, being on a different level of complexity and abstraction, will exhibit laws of a specific nature which have themselves to be the subject of study. This class composes materialists who are not mechanists.

Prof. Compton, in the lectures before us, shows himself to belong to the second school. By a scrupulously careful analysis, frequently hesitating to commit himself, he strives to bring out the relation between his scientific and his religious thinking; in the former, standing fast by strict verifiable evidence, in the latter, supplementing the numerous lacunæ in evidence with general argument based on human and emotional needs. It is clear that there is a vital distinction in criteria between the two modes of thinking, of which Prof. Compton is not too conscious. In this way, he deals with the much discussed question of determinism, with the basis of his belief in a Superhuman Intelligence that guides the destiny of the universe, and with immortality. He concludes that there is a psychic element in the universe standing outside matter and surviving it, an element that, operating along with material indeterminacy, directs the course of human action. It is in fact an assertion of extra-material psychic determinism; and yet, alongside this, he seeks, rather inconsistently it seems, to retain freedom of action for the individual.

The case is well and interestingly argued throughout, but, as with other writings of this nature, the author assumes that in countering the case of the mechanists, he is destroying the materialist point of view. He seems unable to distinguish between the position adopted by the Encyclopædists, the mechanists of the eighteenth century, and that of the modern materialist. Had he done so, he would have recognised that there are in reality several distinct problems of determinism; but if they are to be dealt with as one, then the different levels that fall within its scope must be made clear. There is the sub-atomic level, the mass-particle level, and the human and the social level. To equate concepts at different levels is to miss the essence of scientific abstraction.

Scientific experimentation at the particle level is intrinsically deterministic, and is associated with a particular type of prediction. The language of science, and therefore the language of scientific explanation, formulated at this level, tends naturally to be carried downward and upward in common speech to the sub-atomic and to the social levels. Immediately contradictions seem to emerge. When we talk of human or of sub-atomic determinism, are we talking about something that has a verifiable meaning of the same order as particle-determinism ? What is to be meant by prediction in each of these cases ? When we talk of 'freedom', how is it to be defined, or how are we to recognise it within each of the three categories ? These are questions we must pose and answer before we can be certain that we are using words sensibly or asking sensible questions when we inquire : "Has determinism broken down in the sub-atomic field ? Are we therefore 'free' human agents ?"

The idea that there is a breakdown in detailed prediction does not disturb the materialist, as many imagine, although it has excited the idealists into thinking that they see an escape from the imaginary moral strangulation of a rigid mechanistic determinism. Determinism at the sub-atomic level with its associated 'probability prediction' is a very different story from that at the social level, where the fact that man may frequently predict his own behaviour is a crucial quality of the situation. Prof. Compton, in common with many other outstanding physicists, ought surely to see this, for the nature of the material handled and the appropriate experimental methods are fundamentally different. Conscious living matter has qualities of a totally different order from those either of a particle or a photon. It is an active agent that can think, analyse and experiment. In the problem of 'man performing the social activity science', for example, man ranks as one of the determining forces in the situation. If we are to answer the question : "Is human action predictable ?" we have first to form the appropriate abstractions and devise an experimental technique, in order to create a basis for prediction at that level for this human process, to elucidate the laws exhibited. If man's actions are sometimes accompanied by a subjective sense of free-will, as they undoubtedly are, we have to discover the laws of free-will behaviour. All social predictions (and there are many of the small scale in the commercial and industrial world) are based on such laws. Their distinctive quality is that human beings as active agents form these laws and formulate them. As conscious beings, however, they can become aware of the laws they can make and therefore they can plan their future. That is the link between science and human progress.

When viewed from this angle, 'freedom of man', the subject of these lectures, is not something already existing or to be argued into existence. It is something to be achieved. To rank it with determinism at other levels is to miss its essentially distinctive character.

H. LEVY.

Structure of Metals and Alloys

The Structure of Metals and Alloys
By Dr. William Hume-Rothery. (Monograph and Report Series No. 1.) Pp. 120 + 4 plates. (London : Institute of Metals, 1936.) 3*s*. 6*d*. net.

OF all the recent developments in metallography, the most outstanding has been that which has resulted from the invasion of the physicist and the physical chemist, both of whom have, in the past few years, applied their own methods of investigation more and more to the metals and their alloys. As a result, although most of the ideas reached by the use of the older methods have withstood this attack, other conceptions have had to be modified, and in one or two cases, drastically.

The most recent adventure of the Institute of Metals in publishing a series of monographs, each of which is to deal authoritatively with some special aspect of metallurgical interest, could not, therefore, have commenced with a more suitable one than that under consideration, nor could a more proper author have been selected than Dr. Hume-Rothery, whose own contributions to this particular field of study are well-known. The position of metallography at the common boundaries of so many sciences renders it almost impossible for its workers to maintain contact with all the developments which have a potential bearing upon their own lines of work, and the Institute of Metals and Dr. Hume-Rothery have performed a service to the science of metals which cannot be acknowledged in terms too high.

Assuming merely that knowledge of modern physics and physical chemistry which may now reasonably be expected from the metallographer, the author has, in a manner as simple as the nature of his subject permits, described present-day conceptions of the electronic structure of the atom, the crystalline structure of the elements and their atomic radii, the solid solutions which form the end phases of the equilibrium diagrams and the phases which occur in between. The concluding section of the book is concerned with the imperfections of crystals, a matter of supreme importance to the metallurgist, whose materials are all aggregates of crystals, which in normal circumstance are very far from perfect. It cannot be too strongly stressed, however, that the work is essentially scholarly, and although necessarily written with the needs of the metallographer chiefly in mind, contains matter of the most direct importance to the physicist, the physical chemist and the crystallographer. For many readers the general account given will probably be adequate, but for those who desire to study the subject matter of this monograph still further, the long lists of references to original work will be of first-rate value.

It is inevitable that almost every metallographer will find certain aspects of the work with which complete acquiescence is impossible—to the present writer, for example, there appears to be an inadequate appreciation of the solidity of the structure built up on the basis of what may perhaps be termed classical methods—but there can be no doubt that the author has performed the task assigned to him in a most praiseworthy fashion. Both to him and to the Institute of Metals most sincere congratulations must be offered for the publication, at a price within the reach of all, and at a time when it is perhaps most needed, of a really authoritative account of pioneer work which may well initiate an entirely new era in fundamental, theoretical metallography.

Alpine Studies

The Structure of the Alps

By Prof. Léon W. Collet. Second edition. Pp. xvi + 304 + 12 plates. (London: Edward Arnold and Co, 1935.) 20*s*. net.

In a review of the first edition of Prof. Collet's fascinating account of the building of the Alps (NATURE, 121, 412; 1928), the appeal of his work to mountaineers and holiday-seekers, as well as geologists, was emphasised. That the book should have gone out of print and a revised edition be required is a tribute to its value and interest; also to the rapid progress of Alpine studies. Indeed, as the author states in his preface to this second edition, "a brilliant international gathering of geologists has been engaged in following the Alpine structure in the Western, as well as in the Eastern, Mediterranean regions, and new ideas of the structure of the Alpine Range have been presented". Prof. Collet has therefore added a new Part 6, consisting of six short chapters dealing with the Apennines, the mountain-arcs of Corsica, Sardinia and Elba, the Alpine Chain of southern Spain and the Balearic Islands. As many of these areas are becoming increasingly popular as tourist resorts (and for residence), Prof. Collet's descriptions of the rock-structures and their effects on the scenery will be highly appreciated.

The increase in length of the book thus necessitated has been to some extent offset by a reduction of detail in some of the chapters, such as that on the Jura Mountains. In this regard, the author's policy will doubtless be welcomed by the non-technical reader, especially as opportunity has been taken to clarify parts of the text of other chapters, to add new diagrams, and to rewrite the chapters on Mont Blanc and the Aiguilles Ranges (to the knowledge of which Prof. Collet has himself made noteworthy contributions).

Some of the minor blemishes of the first edition have been removed. Students are no longer told (without supporting evidence) that the higher Pre-Alps represent a small part of Africa resting on Europe. Indeed, the new edition of the book conveys the impression of being less extremist in the matter of belief in the long-distance travel of overthrust sheets (*nappes*) of the earth's crust. An approach to the more moderate views of the Austrian geologists is shown by the attribution of the East Alpine sheets to Kober's *Zwischengebirge* (or *Zwischenmassiv*). It is perhaps unfortunate that the author introduces the inelegant term "Betwixt Mountains" for these masses; for, although it is a literal translation of one of Kober's expressions, the areas involved are not always mountainous (as witness, the country within the Carpathian arcs). A better English equivalent, "median mass", has been in use for some years. It is a pity also that the termination *-ides* has been retained in such words as Metamorphides, Dinarides (*G. Dinariden*). Astronomers do not write "Leonides", or cause confusion by trying to pronounce the word!

But, whether or not we agree about these matters of detail, or about the views of the extremists of the Nappe theory school, Prof. Collet's volume is unquestionably of great value.

P. G. H. B.

Phenomena in High-Frequency Systems

By August Hund. (International Series in Physics.) Pp. xv + 642. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 36*s*.

THIS well-packed book of specialised information does not appreciably overlap the author's previous "High-frequency Measurements", and is intended to give a comprehensive and up-to-date discussion of the rapidly varying phenomena which the electrical communication engineer controls for useful ends, possibly often without understanding entirely the basic physical principles.

The thermionics of gaseous and vacuous valves introduces the subject matter, after a prefatory acknowledgment of the pioneer observers and developers of electromagnetic theory and electronics; generators of high-frequency power, modulators, demodulators, rectifiers and amplifiers receive detail treatment, and electro-striction is made an important division of the main subject; the serious aspects of electromagnetic theory then find a place, with applications to the more practical phenomena associated with propagation through ionized space and the technique adopted in directing radiated energy.

There are useful appendixes, but the last chapter on filters seems incomplete and redundant in view of the more comprehensive treatises now being issued. The author has a critical sense of the work of others, and his 'display' diagrams are specially helpful for the elucidation of the operation of complex valves and antennæ systems; the reviewer has still to find an explanation of what happens at the corners when a long wire is folded up to form a directive antenna.

L. E. C. H.

Die Allotropie der chemischen Elemente und die Ergebnisse der Röntgenographie

Von M. C. Neuburger. (Sammlung chemischer und chemisch-technischer Vorträge, herausgegeben von Prof. Dr.-R. Pummerer, Neue Folge, Heft 30.) Pp. 106. (Stuttgart: Ferdinand Enke, 1936.) 9.30 gold marks.

THE author gives an account of all the elements which have been supposed to exist in allotropic modifications and, by taking account of the latest methods of investigation, particularly X-rays, he decides which of them actually exhibit allotropy. The crystal forms of the allotropes are specified quantitatively, with very complete references to literature and diagrams.

Although the text is commendably brief and clear, it fails in one or two cases to supply information which the reader would like to have, such for example as to whether explosive antimony is an allotropic form or not. The author, in fact, is concerned almost entirely with the results of X-ray analysis, and where this is not applicable he tends to remain silent. In its field, the book is of very considerable value and serves as a reliable guide through a large mass of data, much of it contradictory. It states clearly in which cases allotropy has been established and where it has not, and in the doubtful cases it presents the evidence in an unprejudiced way.

Soils:

their Origin, Constitution and Classification; an Introduction to Pedology. By Prof. G. W. Robinson. Second edition. Pp. xvii + 442 + 5 plates. (London: Thomas Murby and Co., 1936.) 20*s*. net.

PROF. ROBINSON'S novel treatment of soil science evidently 'met a long-felt want', for a new edition has been required in less than four years. The rapidly developing subject of pedology has many more intimate links with other branches of science than had the older agricultural chemical treatment of soils. At the same time, it bears more closely on those general questions of land classification and utilisation which are becoming increasingly urgent. Surveys and planning must be preceded by careful study of the objects to be classified and their relationships to environmental and historical factors. Prof. Robinson's book shows how far the modern science of soils has been able to go in the interpretation of the formation and behaviour of soils. The geographical and genetic aspects are kept in the foreground throughout, while the more purely technical and agricultural ones are treated very briefly indeed. The book can be strongly recommended to workers in many branches of natural and applied science.

In the new edition the bibliography has been increased and the illustrations greatly improved. Quite recent work on the clay complex, base exchange and soil moisture are fully discussed, space having been gained by omitting the appendix on methods of analysis, which were well handled in Mr. C. H. Wright's recent book.

Official Year Book of the Commonwealth of Australia

No. 28, 1935. Prepared by E. T. McPhee. Pp. xxxi + 971. (Commonwealth Bureau of Census and Statistics, Canberra.) (Canberra: Commonwealth Government Printer, 1936.) 5*s*.

THE new issue of this valuable year book is planned on the usual lines, and even if the call for economy still curtails the size of the volume and curbs the desire of the editor in the presentation of available data, the scope is so comprehensive that little of real importance can have been omitted.

After a summary of the history of the Commonwealth, with the Act of Constitution in full, there follows a chapter on the climate and meteorology provided with statistics, graphs and a rainfall map. Among the many chapters of administrative and financial statistical detail, there is especially full treatment of vital statistics as disclosed in the census of 1933. It appears that the birth-rate in Australia has fallen to the relatively low figure of 16·4 per 1,000 from 27·1 in 1901. If this is low, the death-rate of 9·3 per 1,000 is one of the lowest in the world, so that the natural increase is still higher than in European States excluding Russia, the Netherlands, Spain and Italy. Increase by immigration, which was so high as 32,000 in 1927, fell to about 1,000 in 1934 after four years of actual loss by emigration. The volume has full particulars of agricultural production and mineral output. New Guinea is included in the survey. There is a useful bibliography.

Canadian Water Power Developments during 1935

By Dr. Brysson Cunningham

THE series of reports[1] recently issued by the Dominion Water Power and Hydrometric Bureau indicate that, during the year 1935, there was steady progress in the development of water power in Canada, resulting in a substantial addition to the aggregate power installation, which on December 31 last reached a total of 7,909,115 horse power, as compared with 7,547,035 horse power at the close of the preceding year. The accompanying table shows the distribution of power among the provinces of the Dominion. It is pointed out that while the increase in generating capacity is noteworthy, there is even greater significance in the continued growth of the demand for power, as reflected in the monthly records compiled by the Dominion Bureau of Statistics, which indicate a steady increase, month by month, over the figures for the previous year, amounting in general to more than 11 per cent. This increase, it is stated, is not confined to any one part of the Dominion but extends from the Atlantic to the Pacific.

Available and Developed Water Power in Canada, January 1, 1936.

Province	Available 24-hour power at 80 per cent efficiency		Turbine installation (h.p.)
	At ordinary min. flow (h.p.)	At ordinary six months flow (h p.)	
British Columbia	1,981,000	5,103,500	718,497
Alberta	390,000	1,049,500	71,597
Saskatchewan	542,000	1,082,000	42,035
Manitoba	3,309,000	5,344,500	392,825
Ontario	5,330,000	6,940,000	2,560,155
Quebec	8,459,000	13,064,000	3,853,320
New Brunswick	68,600	169,100	133,681
Nova Scotia	20,800	128,300	116,367
Prince Edward Island	3,000	5,300	2,439
Yukon and North-west Territory	294,000	731,000	18,199
Total	20,347,400	33,617,200	7,909,115

Among the chief installations inaugurated in 1935 were three additional units of 66,000 horse power each at the Canyon station of the Ontario Government on the Abitibi River, bringing the station up to its full capacity, as designed, of 330,000 horse power, and the addition of two 50,000 horse power units at Beauharnois, on the St. Lawrence River, by the Beauharnois Light, Heat and Power Company, bringing the number of units at that station up to eight, with an aggregate capacity of 400,000 horse power. This latter installation, which has been already described in NATURE[2], comprises very important control works on the St. Lawrence River, with the diversion of an authorised quantity of 53,072 cu. ft. per second from the river flow. These control works have now been completed. The MacLaren-Quebec Power Company has added a fourth 30,000 horse power unit to the High Falls installation on the Lièvre River, bringing it up to its total ultimate capacity of 120,000 horse power.

It is, accordingly, evident that the activities of the various companies and authorities engaged in hydro-electric exploitation continue unabated, but there is still ample scope for further development, since it is reliably estimated that Canada has an aggregate available water power totalling 20,347,400 horse power under conditions of ordinary minimum flow, and 33,617,200 horse power ordinarily available for six months of the year. Even these figures are probably understatements, for on the basis of the actual water-wheel installation throughout the Dominion, there is a realised excess of 30 per cent over the calculated quantities, so that it may confidently be stated that the actually recorded resources of the Dominion admit of a turbine installation of some 44,700,000 horse power, of which only about 18 per cent has so far materialised. Yet, even this relatively small percentage places Canada with its 722 horse power per 1,000 inhabitants in an outstanding position amongst the water power using countries of the world. The provinces of Ontario and Quebec jointly possess more than 81 per cent of the total developed power, representing, in Quebec, a proportion of 1,258 horse power per 1,000 inhabitants, and in Ontario, 712 horse power per thousand.

It is interesting to note the uses to which the power is put. Almost 88 per cent of the total hydraulic development is utilised in central electric stations, and represents more than 95 per cent of the main generating equipment of the industry which, in turn, generates more than 98 per cent of the total electricity produced for sale in Canada and for export. Although not specially remarkable in size or power, the view in Fig. 1 is interesting as an example of a recent development at Sault Ste. Marie, on the St. Mary River, Ontario. The installation is of 28,050 horse power and belongs to the Great Lakes Power Company. Another channel of absorption is the pulp and paper industry, Canada's predominant manufacturing activity, which has hydraulic installations of 605,346 horse power and a motor installation for operation by hydro-electricity aggregating more than 1,029,000 horse power, or a combined mechanical installation of more than 1,634,000 horse power. In addition, the industry purchases large quantities of electricity from the central electric stations for use in electric boilers. Fig. 2 shows a development of 56,250 horse power at Smoky Falls on the Mattagami River, belonging to the Spruce Falls Power and Paper Company Ltd.

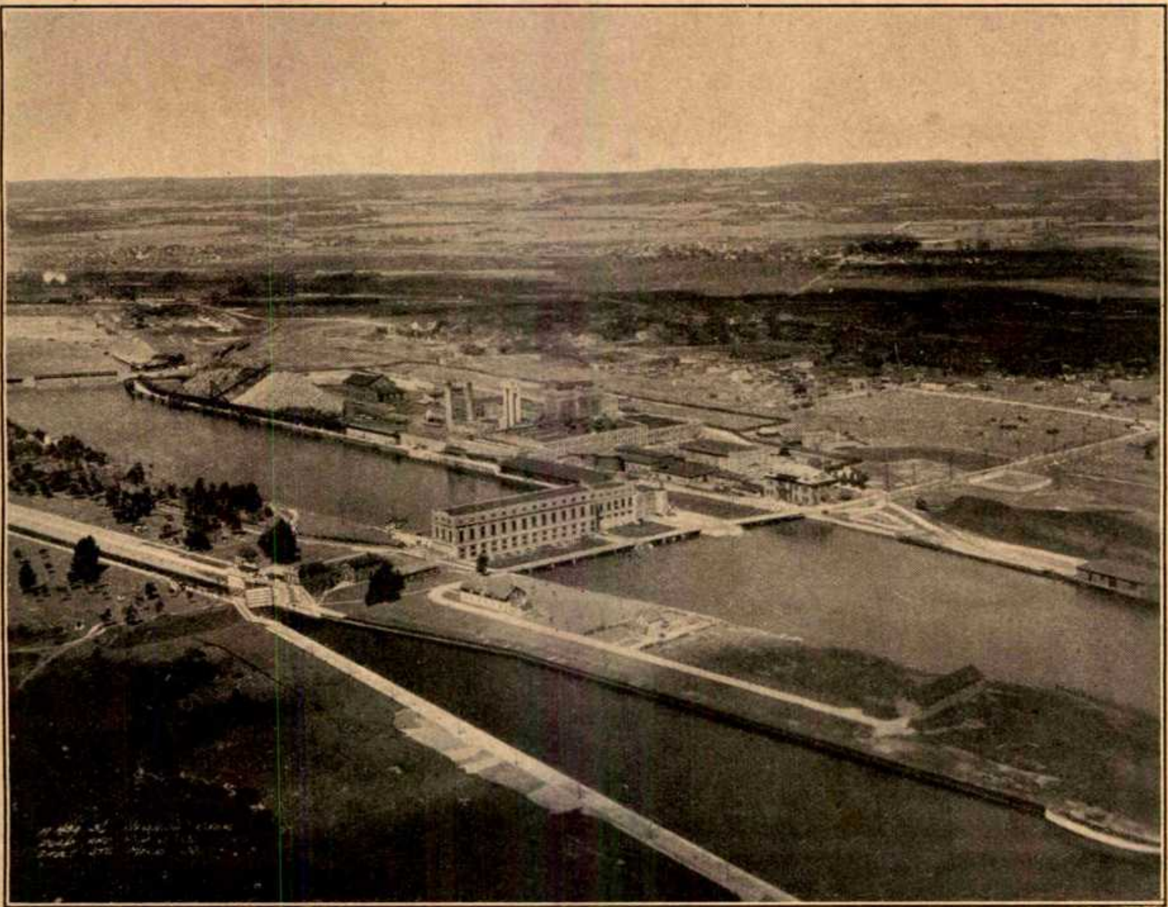

FIG. 1. Sault Ste. Marie development, St. Mary River, Ontario. 28,050 horse power. Great Lakes Power Co., Ltd. By courtesy of the Canadian Official News Bureau, London.

Water power is also a valuable aid to the mineral industries, and indeed its importance in this respect can scarcely be overstated. The convenient location of ample supplies of hydraulic power economically adjacent to mineral fields and centres of mining activities, and the consequent low price generation of power have been dominant factors in the successful development of the mining industry in Canada. A particularly notable feature is the large volume of lower grade ore which can be, and is, profitably mined as a result of the low cost of power. In the latest Annual Report issued by the Dominion Bureau of Statistics on the mineral production of Canada, it can be seen that the Dominion produces, normally, about 90 per cent of the world's supply of nickel, 60 per cent of its asbestos, nearly 35 per cent of its cobalt, 12 per cent of its gold and lead, 10 per cent of its silver, 15 per cent of its zinc and 13 per cent of its copper, besides being one of the major producers of the platinum metals and of aluminium, radium and uranium. Moreover, there is a wide field among the rocks of the great Laurentian Plateau or Pre-Cambrian Shield for the further exploitation of mineral deposits, remarkable alike as regards variety and extent, and this area contains nearly 60 per cent of Canada's available water power, an endowment which is highly favourable to economic development. The Report of the Water Power Bureau affirms that "so far as information is available, there is no present or prospective mineral area, with the exception of some of the coal fields of the middle plains, where hydraulic energy cannot be made available as demand arises".

One of the most enterprising administrative organisations of the Dominion is the Quebec Streams Commission, which continues to maintain efficiently the desired regulation of flow on all the controlled rivers by means of its extensive system of storage reservoirs in various parts of the province. The Commission now controls seventeen reservoirs, some of them of very considerable size. During the year under review, important legislation was passed by the Quebec Provincial Government extending the powers and activities of the Commission to the actual development and utilization of water power sites, the operation of hydro-electric installations and the production and transmission of hydro-electric energy, as also its purchase from other central electric stations and its re-sale to municipalities and other consumers. A new Commission, the Quebec Electricity Commission, has been created with wide powers in regard to the regulation of operations, and the levying of rates and other matters connected with the production and distribution of electrical energy in the Province.

With these evidences of the energetic exploitation of its resources of water power, so realistically described in French as *la houille blanche* (white coal), it can be seen that Canada is more than counterbalancing its deficiency in natural fuel. At a moderate estimate of equivalence, the present hydro-electric installations, on the record of their output for 1935, are shown capable of effecting a saving in coal of 19 million tons per annum, and since owing to the lack of geological coal deposits, the highly industrialised Provinces of Ontario and Quebec are under the necessity of importing supplies, it is obvious that the substitutionary power is of the highest importance to their commercial welfare.

Indeterminism and Free Will

By Prof. E. Schrödinger

IT has become the orthodox view of physicists to-day, that the momentary state of a physical system does not determine its movement or development or behaviour, to follow; Nature is supposed to be such that a knowledge of state, sufficiently accurate for sharp prediction of the future, is not only unobtainable but also unthinkable. All that can be predicted refers to a large number of identical experiments, and consists in a definite statistics among all the possible developments to follow. The relative margin of indeterminacy (the 'spread' of the statistics) is large for a small system, for example, for an atom; but for large systems the margin is usually, though not necessarily, small, which makes it possible to account for the *apparent* determinacy of inanimate Nature.

Many eminent scientific workers, especially physicists, have tried to play with the idea that the *apparent indeterminacy* of animate Nature, that is, of living matter, might be connected with the theoretical indeterminacy of modern physics. What makes this play so fascinating and thrilling is evidently the hope (whether outspoken or concealed) of extracting from the *new* physical dogma a *model of free-will*, which the *old one* would refuse to yield. I consider this hope an illusion, for the following general reasons.

When observed objectively in other creatures, free-will actions do not call for a special 'indeterminist' explanation any more than other events. When two persons (or the same person on different occasions) react differently under apparently the same conditions, we feel compelled to account for it, whether the reaction is a passive or an active one; by a real, though unknown, difference of conditions, including, of course, character and temporary disposition on the part of the reacting persons. A poet unrolling before us the objective picture of free-will actions is just as concerned about proper causation (here called motivation) as the classical physicist was for inanimate Nature.

On the other hand, when regarded as a fact of self-observation, free-will has quite a different standing from scientific experience. The two are, as it were, in different planes, which do not intersect. Self-observed free-will I would analyse into *two* facts. First, indeed, a prediction, but *not* based on previous experience, certainly not in the way in which scientific prediction is. If I am the actor, I just *know* what is going to happen, and that, apart from pathological cases, with the greatest amount of certainty which is ever met with in life. The *second* fact is a moral one: I feel responsible for what happens.

Now, it is true that this *absolute* prescience is a matter only of the very last moment before or when the action sets in, which it rather accompanies than precedes. Before that there is frequently doubt and even entire ignorance ('hesitation'). This antecedent period, together with the remarkable feeling of responsibility, entails the idea of *choice* between different possibilities for which a clue is sought in the modern views of physics. If that were right, it would mean *either* one of two things. First, that the laws of Nature are after all at "my" mercy. For if my smoking or not smoking a cigarette before breakfast (a very wicked thing!) were a matter of Heisenberg's uncertainty principle, the latter would stipulate between the two events a definite statistics, say 30 : 70; which I could invalidate by firmness. *Or*, secondly, if that is denied, why on earth do I feel responsible for what I do, since the frequency of my sinning is determined by Heisenberg's principle? The new physics does not shift St. Augustin's paradox by a hair's breadth.

In my opinion the whole analogy is fallacious, because the plurality of possible events, in the case of an action under free-will, is a self-deception. Think of cases such as the following: you are sitting at a formal dinner, with important persons, terribly boring. *Could* you, all at once, jump on the table and trample down the glasses and dishes, just for fun? Perhaps you could: maybe you feel like it: at any rate you *cannot*. Then, which of the virtually possible events are to be called possible under the auspices of free-will? I would say, just the one that actually follows.

Against this view cases might be quoted where the decision is really difficult, serious, painful, bewildering, when we are down on our knees before the Almighty to forgo it. But in this He is inexorable! We *must* decide. One thing *must* happen, *will* happen, life goes on. There is no ψ-function in life. I have always considered this having-to-decide as a strikingly close subjective correlate to the classical, the deterministic model of Nature. It ought to be emphasized that modern physics does not compel us to abandon this correlation. The material units which determine the processes of life seem to be large enough for—possibly and even probably—safeguarding the essential course of these processes against any perceptible direct and immediate manifestation of the Heisenberg uncertainty.

The preceding remarks have been elicited by the first page of a highly interesting sketch by Prof. F. G. Donnan, "Integral Analysis and the Phenomena of Life" (Acta Biotheoretica, Series A, vol. 2, Pars 1, 1936; Leyden: E. J. Brill), though not by way of contradiction. Prof. Donnan is not concerned with the question of free-will. His idea is that an organism is to be regarded as a 'historical' system, whose reactions at a given moment are not determined alone by its surroundings and by its momentary state, but also by what has happened to that organism during a certain previous period. This is a highly attractive view, and the mathematical treatment proposed by Prof. Donnan a very suggestive one—even if one should hesitate to agree with the view (which he considers essential) that some of the historical traces are *not* engraved in the momentary state otherwise than by modifying its reactivity.

The Institute of Experimental Psychology at Oxford

THE University of Oxford has recently enacted a statute establishing an Institute of Experimental Psychology, at which active work will be begun in the autumn. Dr. William Brown, Wilde reader in mental philosophy in the University, has been appointed its first director, with Dr. William Stephenson as his assistant. The management of the Institute is in the hands of a committee consisting of the Vice-Chancellor, a representative appointed by each of the boards of the Faculties of Medicine, Literæ Humaniores, Biological Sciences and Social Studies, together with the director.

Thus Oxford has at length officially fallen into step with the movement that has been going on for more than fifty years, the aim of which has been to free psychology from the exclusive tutelage of philosophy, and establish it as an independent, empirical and experimental science. Such freedom, however, does not imply separation, nor can the independence be more than a relative one.

In taking its place among the other natural sciences, the data of all of which provide grist for the philosophical mill, psychology will still look to philosophy, as they do, for the solution of some of the ultimate problems; though it will pursue its own proximate quests by its own empirical line of approach and the use of its own appropriate methods. Grouped together with the other sciences, again, and particularly with the biological and social sciences, there will be much overlapping and interlacing, which can only result in great mutual advantage to them all. Both these points have most wisely been taken into consideration in the constitution of the committee of management of the new Institute.

The foundation of this laboratory at Oxford is in a sense a historic event. For centuries, the University has been the home of philosophy, of which psychology has always been an integral and essential part. In the Middle Ages, Roger Bacon and Duns Scotus, no mean psychologists, stand out amongst its scholars. In the seventeenth century, the 'father' of modern psychology, John Locke, author of the famous "Essay Concerning Human Understanding", was a student of Christ Church. When the Wilde readership was founded in 1898, a distinguished psychologist, G. F. Stout, was appointed to hold it; and he was succeeded by a no less distinguished teacher of the science than William McDougall.

An age-long tradition was there; the conversion of rational into empirical psychology had already begun. But as yet there was no established laboratory in which systematic research could be prosecuted. One is tempted to ask why Oxford should have lagged behind when Cambridge, London, Manchester, Edinburgh forged ahead, in company with most other European and American universities, following the lead of Wundt at Leipzig. Was it opposition from the ancient vested interests of philosophy? Was it the belief that scientific psychology was a mere appendage of physiology? Did the terms of the Wilde readership, excluding experimental psychology explicitly from its purview, stand in the way? Of recent years, at any rate, it was none of these things. Before the Great War, McDougall was able for a time to direct a laboratory, housed in rooms belonging to the Department of Physiology, and having access to apparatus in use there. Solid work had already begun; and, but for the upheaval of the War years and their aftermath, it might have become permanent. But the accommodation was then urgently needed for other purposes, and funds were unavailable; so the project had to be abandoned.

University College of Science
PHYSICS Dept
92, Upper Circular Rd, Calcutta

During Brown's fifteen years' tenure of the Wilde readership, several attempts were again made in this direction; but, though encouraged by much friendly sympathy on the part of the authorities, the same lack of funds and rooms in which to house a laboratory made it impracticable. Last year, however, a generous offer of £10,000 was made through the Wilde reader for this purpose; and it was gladly accepted by the University. The curators of the University Chest will provide the necessary accommodation; and a further sum of £500, together with a grant of £150 a year for five years from the Rockefeller benefaction for research in the social sciences, is to go to the Institute.

Centenary of Darwin's Visit to the Galapagos Islands

Issue of Commemorative Stamps by Ecuador

DISTINGUISHED men of science have, before now, been commemorated on postage stamps by countries sufficiently civilized to value their achievements, but it does not appear that any particular event in the history of science has hitherto been celebrated in this way. It has been left to the Republic of Ecuador to mark, by the issue of a special series of stamps, the centenary of a critical point in the development of the evolution theory. It was on September 16, 1835, that Darwin first landed on Chatham Island in the Galapagos group, where, as he wrote in his "Journal of Researches", "we seem to be brought somewhat near to that great fact—that mystery of mysteries—the first appearance of new beings on this earth". The influence of what he saw there on the later development of his thought is now a commonplace of biological teaching, although some modern writers on evolution might be well advised to read again his own account of his observations and the conclusions to which he was led.

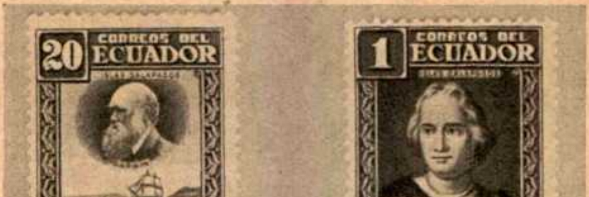

FIG. 1. Stamps issued by the Ecuadorean Government in commemoration of the centenary of Darwin's visit to the Galapagos Islands in the *Beagle* in 1835.

The six stamps which are here reproduced bear designs associated with the islands or with Darwin's visit, the introduction of a portrait of Christopher Columbus being apparently suggested by the Ecuadorean name for the group, "Archipelago of Colon". The portrait of Darwin is taken from a well-known photograph now hanging in Down House; it represents him in his old age, and is probably that by which he is best remembered, although at the time of his visit to the Galapagos Islands he was, of course, a young man of twenty-six years. A view, presumably representing some place in the islands, has a group of coconut palms in the foreground. If this is correct, it indicates a change in the flora since Darwin's time, for he notes in his "Journal", "I saw nowhere any member of the palm family". Two of the designs represent reptiles characteristic of the islands, one of the land iguanas and one of the giant tortoises from which the group takes its name. How many zoologists, one wonders, associate "Galapagos" with the familiar but etymologically obscure word "carapace"?

It is important to remember that one of the things that struck Darwin on visiting the islands was the abundance of individuals, especially of some of the larger reptiles. This density of population has now become a thing of the past, and the accounts of recent travellers make it clear that unless adequate protection can be given, the disappearance of this unique fauna is only a matter of time. It is therefore a subject for congratulation that the Ecuadorean Government has taken an enlightened view of its responsibilities. It has declared the greater part of the archipelago a Nature reserve, in which no hunting or collecting is allowed except by special permission for scientific purposes. Further, a list has been drawn up of the species more immediately threatened, and the killing or capture of these is prohibited, except that the inhabitants may kill some of them for food.

Many scientific bodies on both sides of the Atlantic have expressed their approval of the steps taken, and have offered to co-operate in rendering them effective. A committee of the British Association, under the chairmanship of Sir Edward Poulton, is at present considering what can be done to organise this international co-operation with the Ecuadorean Government.

W. T. CALMAN.

Obituary

Prof. A. A. Bowman

BY the death on June 12 of Prof. A. A. Bowman at his home in Glasgow, British philosophy has lost one of its most effective and attractive personalities.

Prof. Bowman was fifty-three years of age. Except for the period of the War, he had spent his life in the study and teaching of philosophy, first in Glasgow, then in the United States, finally again in Glasgow. He took his degree in classics and philosophy: and after a post-graduate year in Germany, he served his apprenticeship to teaching in Glasgow. In 1910 he was elected professor of logic at Princeton, New Jersey, becoming later administrative chairman of the Department of Philosophy. In 1926, at more than a little material sacrifice, he accepted a call to return to his old University. For one year he held the chair of logic: and from 1927 until his death the chair of moral philosophy. At no time in the long history of that illustrious chair has its holder exercised a stronger personal influence upon his students, upon the University as a whole, and upon Glasgow and the west of Scotland, than Bowman exercised during his short tenure.

Bowman was profoundly a man of peace, and ardent in service of its better organization. The War, however, especially the last months of it, was one of the decisive experiences of his life. He was in the United States. But from the beginning of the War he was restless. In 1915 Princeton gave him leave of absence. The British authorities in the United States, thinking him (quite rightly) medically unfit for active service, refused to recruit him. He came home at his own expense, found some complaisant medical officer to pass him for home service, then, being in the army, badgered his superiors until finally they let him go to France. After a few months campaigning, he was captured in the Lys break-through of April 1918 and sent to a prison camp. That, which seemed to be the end of his service, proved in fact to be his opportunity. Conditions in the camp were deplorable. Bowman's fluency in German made him the natural centre and unofficial leader of the camp. With tremendous resolution, he threw himself into the task first of improving those conditions through negotiation with the German authorities, and then of raising and maintaining the morale of his fellow prisoners. His main instrument for that purpose was a system of tutorial classes which had to be carried through without books or material or facilities of any kind; indeed, with almost no other resource than his own erudition and the persuasiveness of his teaching. He gave lectures and instruction in literature, in philosophy, in contemporary history (especially German and Russian), and in the history of art; and on groups of men quite unfamiliar with these themes, he made a profound impression. He taught them really to save their souls; and he was inspired in the task. That experience sharpened and developed his powers of leadership and of public speech. He had always been a good teacher; the prison camp made him one of the most brilliant and powerful expositors of his time.

Both in the United States and in Scotland Bowman had immense influence. Of slight and even frail physique, he had superb spiritual energy and insight, unshakeable courage, and, as has been noted, quite unusual powers of expression. Scholarship was natural to him: and although his flair was for speculation at once bold and thorough, it was always backed by solid learning. All his life he was an ardent student of classical and of modern literature. He had read widely in social theory and history. He was a good critic of painting. Especially in later years, his studies in the philosophy of religion had drawn him into the field of cultural anthropology, in which he had a vast and intimate knowledge of a great variety of primitive civilizations. All this equipment he brought into fullest play in the ordinary business of his crowded class-room. His students, indeed any audience which he addressed, fell instantly under his spell. For his learning, his humour and his eloquence were no more than the instruments of a man of richest personal quality—of deep insight, of rare imaginative power, and of profound moral and social convictions. In philosophy, he held by the Idealist tradition in which he had been nurtured. He gave it a metaphysical form of his own which his early teachers would have found strange. But he never moved from their conception as to the nature and importance of the issues with which philosophy is concerned. In his hands philosophy was a way not only of thought but also of life. He had worked out his system in the grand style, compact, articulate, thorough and comprehensive, and he presented it with uncommon power.

Bowman's great work was done in the class-room and on the public platform. The tale of his publications is small: a volume of sonnets—the fruits of his prison camp experience—two or three pamphlets and a few articles in learned journals. Happily there is a bigger book almost ready for the press; and it may be hoped that in the large mass of manuscript material which he has left, enough will be found in readily publishable form to give to others than his own students, some idea of the reflections of one of the most original, interesting and courageous minds of our time. H. J. W. HETHERINGTON.

Prof. Margaret Benson

PROF. MARGARET BENSON, whose death on Saturday, June 20, is mourned by a wide circle of friends, is known best to botanists as one of the leading palæophytologists of the last generation. Much of her early work on fossils, which began about 1904, has long been incorporated into the text-books; but it is only a year since she published her last paper on the subject. Her best work was done at a time when the technique of fossil cutting was in its infancy, and for years she cut her own sections at a small lapidary bench in a shed in the grounds of the Royal Holloway College, with a cutting machine worked by a gas engine. She left her valuable collection of fossil slides to the College.

Prof. Benson's industry and single-mindedness were quite exceptional, and were combined with a very real flair for knowing what a fossil might yield and how a structure might be interpreted. She was trained in research at Newnham College, Cambridge, and University College, London, and her early work there on the embryology of Amentiferæ, for which the D.Sc. of the University of London was conferred on her in 1894, is now a classic. In October 1893 she was appointed head of the newly founded Department of Botany at the Royal Holloway College. The Department flourished under her, and in 1912 the University conferred on her the title of University professor of botany, which chair she held at the College until her resignation in 1922.

Prof. Benson was a great traveller and collector; and the botanical garden, museum, herbarium and well-stocked laboratories of her College to-day bear witness to her indefatigable enthusiasm and wise foresight. In the Michaelmas term of 1897 she was granted leave of absence in order to visit the professors of botany of Brussels, Heidelberg, Tübingen, Basle, Strasbourg and Paris in their respective laboratories during term. This tour she made with the view of securing the best information for the equipment of a botanical laboratory. In later years she made two journeys to the antipodes, and on both occasions brought back quantities of valuable specimens. Her botanical work is of enduring value, and she inspired many generations of students with a love of the subject. E. M. B.

Prof. A. A. Noyes

THE death of Arthur Amos Noyes, director of the Gates Chemical Laboratory at the California Institute of Technology, which occurred at Pasadena on June 3 as the result of an attack of pneumonia at the age of sixty-nine years, has deprived physical chemistry of another of its pioneers of the Ostwald school. Noyes may be regarded, indeed, as the American prototype of Sir James Walker, who died last year. Just as Walker was Ostwald's first British student at Leipzig, Noyes was the first American. Of them, Ostwald remarks in his autobiography: "Both are not only distinguished as investigators and teachers, but belong also as men to the best examples of this diversified race".

For nearly twenty years the research laboratory of physical chemistry of the Massachusetts Institute of Technology, which Noyes directed and to which he personally contributed half the expenses of maintenance, was the centre of this branch of science in the United States, and many of the leading American physical chemists may be counted among his students. His own contributions to the ionic theory of electrolytes and to the principles of qualitative analysis were of primary importance in the modern development of these two fields.

Modesty and thoroughness were the chief characteristics both of Noyes' work and of his character. He sought no honours: he leaves many friends.

JAMES KENDALL.

WE regret to announce the following deaths:

Mr. Arthur D. Carey, known for his explorations in Central Asia, for which he was awarded the Founder's Medal of the Royal Geographical Society in 1889, on June 11, aged ninety-one years.

Prof. Ira E. Cutler, emeritus professor of zoology in the University of Denver, on May 25, aged seventy-three years.

Prof. W. E. Dalby, F.R.S., emeritus professor of engineering in the City and Guilds College, Imperial College of Science and Technology, University of London, on June 26, aged seventy-two years.

Prof. Ivan Hönl, professor of bacteriology in the University of Prague, known for his work in combating the scourge of tuberculosis in Central Europe, on June 7, aged seventy years.

Mr. Frank Merricks, past-president of the Institution of Mining and Metallurgy, and a member of the Geological Survey Board in 1920–26, on June 8, aged seventy years.

Sir Charles Nathan, C.B.E., member of the Executive Council of the Australian Commonwealth Council for Scientific and Industrial Research in 1927–28, on June 5, aged seventy-six years.

News and Views

Retirement of Prof. W. A. Bone, F.R.S.

AT the end of the present session, Prof. W. A. Bone vacates, under the age limit, the chair of chemical technology at the Imperial College of Science, which he has held for the past twenty-five years. A graduate of Owens College, Manchester, he studied under Prof. H. B. Dixon and later, when lecturer there in chemistry and metallurgy, he carried out those classical investigations into the slow and explosive combustion of hydrocarbons which have done so much to elucidate the mechanism of their oxidation, and enabled him to formulate the hydroxylation theory. In 1905, he became the first Livesey professor of coal gas and fuel industries in the University of Leeds, and there laid the broad foundations of the new branch of science, fuel technology; there also, in collaboration with McCourt, he invented and developed surface combustion. At South Kensington, Prof. Bone was faced in 1912 with the task of building up a new Department of Chemical Technology, and under his inspiring leadership a research school of world-wide reputation has been created. His field has covered high-pressure explosions and gas reactions, flame spectra, the study by high-speed photography of flame movements in gaseous explosions, the chemical constitution of coal and gas reactions in the blast furnace. At a dinner on June 17, given in honour both of Prof. Bone and Mr. W. C. Hancock who is also retiring from the lecturing staff of the Department, a distinguished gathering including many old colleagues and students assembled, and suitable presentations were made. Fortunately Prof. Bone's retirement does not mean the ending of his scientific activities, for the College authorities, strongly supported by industry and other outside bodies, are providing a new research laboratory in which he will be enabled to pursue those investigations on which he is still actively engaged.

Société de l'Industrie Minérale: Foreign Members

AT a general meeting of the Société de l'Industrie Minérale, St. Etienne, held on May 24, it was decided that the Society should, for the first time, elect honorary members, the terms of the modified statute being that "the title of Honorary Member can be given by the General Meeting to persons of foreign nationality who have promoted the mineral industry or the society by their works". The first elections under the new statute are: Sir Robert Hadfield; Dr. C. E. Guillaume, director of the International Bureau of Weights and Measures; Prof. L. Denoël, professor of mining in the University of Liège; and Prof. P. Fourmarier, professor of geology in the University of Liège. The Société de l'Industrie Minérale, which was founded in 1855, is one of the leading associations of French engineers, and has a roll of nearly two thousand members.

Meyer Medal for Plant Introduction

THE Meyer Medal of the American Genetic Association, for distinguished service in plant introduction, was presented on June 13 to Mr. P. H. Dorsett, who for more than forty-five years has been associated with the scientific work of the U.S. Department of Agriculture. Mr. Dorsett was instrumental in bringing together the largest collection of soy bean varieties that has ever been made. Two expeditions to China were undertaken to make this collection. On the first trip Mr. Dorsett and his son, the late James Dorsett, collected more than two thousand samples from Nanking and its vicinity. On the second expedition, Mr. Dorsett and Dr. William J. Morse, soy bean expert of the U.S. Department of Agriculture, collected more than six thousand samples which were sent to the United States for test. A total of some two thousand distinct varieties of soy beans was obtained from these samples. These are being tested to determine their value to the American farmer. Some of them are already being widely used. The soy bean is a relatively new plant immigrant in the United States, but in 1935 five and a half million acres were planted with it, and forty million bushels of the dry beans were harvested. Mr. Dorsett also took part in three expeditions to obtain new varieties of plants to Brazil (1913–14) and to the West Indies in 1927–30. He was instrumental in bringing into the U.S. valuable citrus varieties and many rare ornamental plants. The Meyer Medal is awarded at intervals by the Council of the American Genetic Association for distinguished services in plant introduction. It is named in honour of the late Frank Meyer, pioneer plant explorer of the U.S. Department of Agriculture, and had its origin in a fund left by Meyer to his fellow workers in plant introduction, who decided to use it for this purpose. Meyer spent the last nine years of his life in plant explorations in China. Among previous recipients is Mr. H. N. Ridley, who was responsible for the introduction of Para rubber into the East Indies.

Newton Manuscripts

AN interesting sale of manuscripts is advertised by Messrs. Sotheby and Co., 34 and 35 New Bond Street, on July 13 and the following day. Readers of NATURE may remember the "Portsmouth Papers", strictly a "Catalogue of the Portsmouth Collection of Books and Papers written by or belonging to Sir Isaac Newton", published by the Cambridge University Press in 1888. The then Earl of Portsmouth presented the scientific part of these papers to the University, and an influential syndicate of the University issued a catalogue of the whole, and took a copy of the more important letters that it did not keep, and returned these to Lord Portsmouth. The Portsmouth family, which has a connexion with

Newton, has put the manuscripts, or such as they have now, in the hands of all serious workers, from Horsley to L. T. More. Viscount Lymington, the heir of the Earl of Portsmouth, has now instructed Messrs. Sotheby to sell them. It might thus seem that there was little except personal matters to find. Many of the letters have been published, accurately or inaccurately, whole or in part, in various well-known sources. But the list includes, for example, such items as "three thick folio volumes", which we did not know of, relating to the Mint and containing documents in Newton's hand. It makes one leave in suspense the Cambridge report, that "Newton's manuscripts on Alchemy are of very little interest in themselves", probable as this may seem in itself, and though the syndicate contained one notable chemist. Also Messrs. Sotheby have added some celebrated portraits to their list. The sale should be well attended; for though most of the contents that are valuable are available, many would like a copy of Newton's beautiful handwriting and that of his contemporaries, apart from those that contemplate a more extensive purchase.

National Inland Water Survey

THE first Annual Report of the Committee appointed in January, 1935, jointly by the Minister of Health and the Secretary of State for Scotland, "to advise on the Inland Water Survey for Great Britain, on the progress of the measures undertaken and on further measures required and, in particular, to make an annual report on the subject", has been awaited with keen anticipation in many quarters, and especially by those engaged in the use and exploitation of the water supplies of Great Britain. It was scarcely to be expected, however, that during the first year of its existence, the Committee would be able to achieve any remarkable results. Its first duty was, naturally, to review the existing conditions and to ascertain the extent to which processes and methods in vogue could be adapted to some uniform and standardized system of procedure. The purpose of the survey, as set out in the Report now issued (London: H.M. Stationery Office. 3*d*. net.), "is to correlate the information at present obtained from all sources, to extend and increase the sources of information, and to make the information readily available for the use of the interests concerned". This has involved exploratory investigations in various directions and the issue of inquiries, which took the form of a detailed questionnaire (reproduced in an appendix to the Report) to which replies have been received from about 3,000 bodies and persons. The replies show that there is a good deal of information available, but that it is varied in type and date, is insufficient and lacks co-ordination and distribution—an endorsement of the conclusions arrived at by the British Association Committee in its report to the Leicester meeting, 1933.

THE present Committee has, accordingly, directed its attention to the means by which an improved system of gauging and recording could be attained. At the same time, it has been conscious of the desirability on economical grounds of adopting as gauging stations a number of structures not originally designed for the purpose, and of obtaining measurements from weirs of a type perhaps not best suited to the end in view. It is of opinion, as advocated in NATURE (Nov. 5, 1932; and again, Aug. 4, 1934), when the matter was first under public consideration, that the Catchment Boards of England and Wales, established under the Land Drainage Act, 1930, are the appropriate bodies to instal gauging stations on rivers and to make and record the measurements of the flow of the rivers which they control. The co-operation of the Catchment Boards has therefore been sought with results which are described as encouraging, and, as there is a large area in England and Wales not yet under the jurisdiction of any catchment board, the Committee has concentrated attention for the time being on areas for which Catchment Boards have been appointed. As regards underground water, the aid of the Geological Survey has been enlisted with the approval of the Committee of the Privy Council for Scientific and Industrial Research. In estimating the value of the existing gauging stations for measuring overground water, an examination has been made of three selected rivers—the Nene, the Thames and the Clyde—and a section of the Report deals with each of them in detail. After setting out its proposals for the publication of data, the Committee concludes the Report with an expression of satisfaction at what it has been able to accomplish in the first year of its existence.

Britain's Largest Hydro-Electric Development

AN aggregate of 102,000 kilowatt of plant is installed in five power stations in Kirkcudbrightshire and Wigtownshire in the south-west of Scotland. When the Water-Power Sources Committee presented its report in 1924, this portion of Scotland was defined as a place where there were possibilities of water-power development, but it was not surveyed as no commercial outlet for the power could then be visualized. The formation of the Grid, by providing the necessary power outlet, showed how a commercial application was possible, and the present hydro-electric scheme was developed as an important factor in the Central Scotland Grid scheme. In the *Electrical Times* for June 25 there is a detailed account of this scheme, called the Galloway Water Power Scheme, which generates the greatest amount of hydro-electric power of any station in Great Britain. In any power scheme the peak units are by far the most expensive. With steam generation, for example, a large amount of plant capacity has to be provided to cover the period of maximum demand. Daily peaks also occurring at regular intervals are expensive owing to the stand-by coal required. In these circumstances, we can see that hydro-electric plant, which can pick up and drop load at very short notice either in normal operation or in emergency, is a very valuable asset. The Galloway undertaking is unique amongst power stations, as it was planned and carried out as a peak load station instead of supplying the usual basic load. It has already proved valuable during the sharp rise and fall of the Glasgow industrial load at the midday dinner hour and other similar occasions. It is satisfactory to learn that after the results of the first twelve months' operation of the first half of the scheme, which includes the two power stations of Tongland and Glenlee, having plant aggregating 57,000 kilowatt, the financial future of the undertaking seems assured.

"Concerning Human Progress"

DR. H. S. HARRISON was characteristically stimulating in his presidential address to the Royal Anthropological Institute on June 30, when he spoke "Concerning Human Progress". Unquestionably his choice of a topic was apt to the needs of contemporary thought, which may well look to the anthropologist for guidance on such questions as the direction and mechanism of human development. Dr. Harrison's conclusions, however, gave his hearers little cause for complacency. He showed no little courage in electing neither to attempt a strict definition of progress, nor to lay down canons of discrimination between upward and downward, in the direction of change. In the event, however, when once he had pointed out that the idea of progress is a modern growth, which did not affect human development until the latter part of the nineteenth century, this deliberate omission enabled him, speaking more especially as a technologist, to demonstrate the essential opportunism of cultural development in the past, which has moved continually forward, backward and sideways, without knowledge of what the direction might be, and not infrequently has led to a dead end. Social progress, he went on to point out, has had no better guidance; but as codes of conduct and actual behaviour are the objective revelations of the mind of man, individually or collectively, and both the material and immaterial products of the human mind have trespassed far beyond the biological necessities, the question arises whether the mind of man has been moulded in response. Dr. Harrison, quite rightly, stressed the apparent paradox that, so far as the evidence goes, there is little, if any, difference to be discerned in physical character and brain power between the earliest example of *Homo sapiens* and the man of to-day. If we look for the directional factor which might have brought about a change in the heart and mind of man, of those forces which have been put forward as active in organic evolution, use-inheritance alone appears to fulfil the requirement, but is ruled out of court, owing to its general repudiation by the biologist. Hence, Dr. Harrison concluded on a note of pessimism, "the mind of man . . . has little sense of direction, and if it may be said to have an ultimate aim, that aim is too obscure for formulation."

The Osborne Reynolds Ridge

THE recent letters in NATURE from Prof. W. Schmidt and Prof. H. Stansfield, describing their observations of a capillary wave on the surface of water, are a reminder that important published observations may be forgotten for many years. Prof. Stansfield now finds that this phenomenon was described by Osborne Reynolds in 1881. Reynolds produced the wave by dropping oil on water, and also observed it in the open air, perhaps when he was fishing, as he says it looks like a line of gut floating on a river, where the water eddies up to the surface in deep pools. About forty years later, there was fresh activity in the study of moving films. In September, 1921, the late Mr. E. Edser quoted Reynolds's paper at a meeting of the Faraday Society, and described experiments showing that the moving film of oil sets in motion a thin layer of water beneath it. Five years before, in Toronto, Prof. J. Satterly had noticed a 'ripple' which moves up a glass tube in advance of the liquid meniscus, when the tube is being filled from below; this and other effects similar to the Reynolds ridge were under investigation there. Five years later, Burdon of Adelaide published a photograph of oil spreading on the surface of water, clearly showing the Reynolds ridge in advance of the visible oil film; and in the same year, 1926, Edser included this photograph and a discussion of the ridge in Appendix IV of his "General Physics for Students". When the rising generation of physicists see the Reynolds ridge, they should recognize it at once as an old friend.

Syria and Crete: Further Discoveries

SIR LEONARD WOOLLEY'S further report on his excavations in Syria is a striking justification of the prescience which sought in the area at the mouth of the Orontes evidence for the early relation of the civilizations of Crete and western Asia. The evidence which has been brought to light since the dispatch of his first report (see NATURE of June 13, p. 979) carries the story of the Ægean connexions of Syria from *c.* 900 B.C., the point at which the settlement at Tell Sheikh Yusuf begins, back to the Middle Minoan age of Crete, somewhere between 1700 and 1580 B.C. At Tell Atchana, a mound near the bank of the Orontes, half-way across the Amk plain in the rear of the Amanus mountains, Sir Leonard reports in *The Times* of June 25, trial excavations in a single trench, which lasted for no more than a fortnight, produced evidence of the existence in the heart of Syria of a city settlement, which was predominantly Cretan in character, and was deserted entirely not later than the twelfth century B.C. At an earlier stage of its history this city had been ravaged by fire and sword, as was shown by the evidence of the large buildings, of which the fire-scarred remains were uncovered. Here the floors were littered with fragments of pottery, among which Syrian wares were mingled with sherds showing characteristic Minoan *motifs*, as well as with specimens of the art of, at present, unknown provenance previously reported. The evidence indicates that the destruction of the building took place before the Late Minoan age began. The find of a Minoan bronze sword is balanced by a Mesopotamian bronze axe and chisels and cylinder seals. The link between Crete and the site on the Amk plain has yet to be demonstrated; but a clue is afforded by the ridge-top acropolis site at the head of the delta, where surface finds on one hand match the pottery of various periods at Tell Sheikh Yusuf, and on the other include fragments of Mycenæan and Cypriote bronze age wares corresponding with the later levels of Tell Atchana.

Recent Acquisitions at the Natural History Museum

MRS. CONSTANCE THORBURN has presented to the Department of Zoology of the Museum seventeen water-colour drawings of British mammals executed by her husband the late Archibald Thorburn. Purchases for the Department include a collection of small mammals, mostly rodents, including some rare and little-known species from the Cameroons; and a small collection of European birds obtained on their northward migration in April and May by Mr. C. G. Bird, at Rio d'Oro, on the north-east coast of Africa. Dr. C. T. Trechmann has generously presented to the Department of Geology a large and valuable collection (including more than 200 type and figured specimens) of Mollusca collected by him from the West Indies. The Mineral Department has received as a gift from Mr. Arthur Earland sea-bottom deposits collected from the Weddell Sea in the Antarctic by the "Discovery" expedition, together with the crystals of gypsum, calcium oxalate, and the new mineral earlandite which had been picked by him from the samples collected. Among the purchases is a series of minerals from Brazil, including a beautiful, table-cut, strongly dichroic aquamarine, spodumene of three kinds and quartz in many different forms and habits. A series of well-shaped crystals of lapis-lazuli and three iridescent limonites from Queensland also have been bought.

Mathematics in Bombay

A VERY interesting experiment in the teaching of mathematics is being carried out in the University of Bombay. Prof. John Maclean, of Wilson College, has had the commendable courage to break away from the beaten track of academic mathematics by devising a special course for his students, dealing mainly with the uses of elementary mathematical methods in the description of quantitative phenomena. The course forms the subject matter of a recent book by Prof. Maclean entitled "Descriptive Mathematics", which was noticed in NATURE of March 7, p. 382. In the Bombay Intermediate Arts and Science examination in March, alternative papers were set; one being of the traditional academic type, whilst the other, entitled "Statistics and Nomograms", was designed to test the efficacy of the new course. Out of a total of 1,400 students, about twenty took this paper. Its questions cover a wide field, and range from Newton's interpolation formula, probability and frequency distributions to transcendental equations and the construction of various types of nomograms. It will be interesting to study the results of this experiment for, judged by the examination paper in conjunction with Prof. Maclean's book, the new course is certainly designed not only to stimulate interest, but also to render a rigorous presentation of the basic ideas in mathematics much more vivid and powerful than that provided by the stereotyped courses.

Scientific Research in Australia

THE ninth annual report of the Council for Scientific and Industrial Research, Commonwealth of Australia (Canberra: Government Printer, 1936. 4*s*. 8*d*.), covers the year ended June 30, 1935, and gives brief accounts of the work of the various divisions in which the work is organised. Weed problems are receiving a considerable share of attention, particularly on the entomological side, through the introduction and distribution of insects which attack the plants in other countries. Investigations are being initiated into contagious bovine mastitis, a serious disease prevalent in dairy herds throughout the world, and an attempt is being made to establish at a dairy farm near Melbourne a normal herd free from the disease. The rabbit pest and the testing of seeds continue to receive attention, and in addition to its investigations on weed pests, the Division of Economic Entomology has been investigating means of preventing the attack of sheep by blowflies. The Division of Animal Health has discovered new and more effective methods of administering anthelmintics for the control of internal parasites of sheep, while the Division of Animal Nutrition has studied the 'coast disease' of sheep, drought feeding and the processes of wool growth. Soil problems, timber preservation and seasoning, the preservation and transport of fruit and chilled beef have been investigated by other Divisions. Even the brief accounts of these investigations contained in the present report indicate that the work of the Council is making noteworthy contributions to the welfare of the basic industries and occupations of Australia.

Geological Survey of Australia

WHEN the Commonwealth of Australia was established, the administration of mining affairs, including geological work, was left with the six independent States. The consequence is that Australia is to-day the only dominion without a national geological survey, a situation which is viewed with grave dissatisfaction by its scientific workers. Every effort hitherto made to remedy the position has failed owing to official opposition from some, but not all, of the State Departments of Mines. A conference between Commonwealth and State officers, held in Melbourne last month, was but little more successful than any of its predecessors. Political, rather than scientific, considerations appear to dominate the issue, and this further failure to agree upon the establishment of a national body, either by the Commonwealth alone or by the States acting jointly, is greatly to be regretted.

Economic Products of the British Empire

VOL. 34, No. 1 of the *Bulletin of the Imperial Institute* has been published by the Institute itself, but the general format remains practically unaltered. This number contains an important report by the

R265

Imperial Institute Advisory Committee on Hides and Skins on a series of hides prepared experimentally in Southern Rhodesia with the view of improving the material turned out by the natives. It is shown that a simple method of drying the hides which was recommended by the Committee gives excellent results, as it did in the case of earlier experiments in East Africa, and is a great improvement over the ordinary native methods of sun-drying. An article by Mr. M. H. French, of the Tanganyika Veterinary Service, records the work which has been done in that Territory to improve the quality of the clarified butter (ghee) produced there. This product, although little known in Great Britain, is of great importance in tropical regions, since when properly prepared and stored it will keep almost indefinitely under conditions in which ordinary butter turns rancid in a few days. An article by Dr. E. O. Teale, mineral adviser to the Government of Tanganyika Territory, describes recent developments in gold mining in this country. Another article gives a brief outline of the mineral resources of Johore, one of the little-known Unfederated States of Malaya. Alluvial tin ore is being mined in three different areas. In another area iron ore is being mined, and unworked deposits are known to occur in three further regions. Gold and china clay are being produced in small amounts, wolfram has been found in one locality, and prospecting for coal is being carried on in two places.

National Bureau of Standards

A REPRINT from the annual report of the U.S. Secretary of Commerce, 1935, describes briefly the more important of the developments of the Bureau of Standards during the last twelve months. Scientific workers and engineers are making increasing use of its facilities. The testing of supplies and materials has increased by 15 per cent over the previous year. This is partly due to the building activities of various Government agencies. Having received an exceptionally pure sample of the metal gallium, its freezing point was determined and found to be $29 \cdot 780° \pm 0 \cdot 005°$ C. The melting point of this element is so low that the crystals melt to a liquid on a hot summer day. An investigation has been completed on the efficiency of a large number of rust-preventing materials with particular reference to their use in preventing corrosion in aviation engines during storage. Certain types of materials have been found to be extremely effective for this purpose and for use as general rust preventatives. Laboratory tests of numerous types of oil filters show that some of these devices are most efficient in removing impurities formed in the oil during service. Two formulæ were developed for ink powders which make a writing ink superior to the present federal specification. Work has shown that the superior properties of the English clays are apparently due to the presence in them of certain natural fluxes which are not found in American clays. These fluxes have been identified and studies are now being made of American clays modified by the addition of fluxes. A code for the safety glass used in automobiles has been formulated. It was developed by the co-operation of manufacturers and users of glass and motor-cars. It specifies tests for wire glass, heat-treated glass and laminated glass which ensure satisfactory safety glass.

Scientific Horticulture

THE fourth year-book of the Horticultural Education Association ("Scientific Horticulture", from the Editor, Mr. R. T. Pearl, South Eastern Agric. Coll., Wye, Kent, 3*s*. 6*d*. net) presents many helpful contributions. Several papers describe the special considerations of gardening in various parts of England, or discuss the horticultural needs of a particular industry, such as cider-making; and the number of articles which achieve the difficult blend of science with practice shows a gratifying increase over previous year-books. There are also articles which summarize the findings of research stations. Dr. W. F. Bewley writes on "Twenty-one years' Glasshouse Research at Cheshunt", whilst Mr. R. B. Dawson portrays the origin and work of the Board of Greenkeeping Research. Prof. R. J. D. Graham has collected the results of the late Laurence Baxter Stewart on vegetative propagation, and his tables, showing the times and seasons when difficult cuttings may be rooted, will be of very real value to gardeners. Plant pathology has two papers: "The *Phytophthora* Disease of Strawberry" by Mrs. N. L. Alcock and Mr. D. V. Howells, and "The Virus Diseases of Glasshouse and Garden Plants" by Dr. K. M. Smith. Very useful reviews of the present position of research into vernalisation and into photoperiod are given by Dr. O. N. Purvis and Prof. F. G. Gregory respectively. Messrs. W. J. C. Lawrence and J. Newell describe "Seedling Growth in Partially Sterilised Soil", and Drs. Kidd and West issue a warning about the gas storage of apples. They show that the harmful concentration of carbon dioxide in the atmosphere of the store varies with temperature and also with the oxygen content. The president of the Association, Mr. H. L. Jones, chose the subject "Horticultural Education in North Wales" as the title of his address. The contributions are rarely reports of new work, but serve, in an admirable manner, to make available the more abstruse, and often isolated, findings of research in pure science.

Sands, Clays and Minerals

THE April number (Vol. 11, No. 4) of *Sands, Clays and Minerals*, published by Mr. A. L. Curtis, Westmoor Laboratory, Chatteris, once again brings home to readers the fundamental purpose of this magazine. The editorial reiterates that at any rate a partial solution to the problem of unemployment lies in opening up the vast unexploited mineral resources of the British Empire. Numerous industries depend on minerals as raw materials, and increased production leads to increased activity in these industries, with a corresponding fall in unemployment. Certain minerals now being obtained from foreign sources might be produced wholly or in part within the British Empire. Obstacles to optimum development of such resources are not irremovable, though at the present time they loom large. Possibly if the responsibility for economic development were taken from bureaucratic bodies and sharply dissociated from political circles, a more rapid advance could be achieved. It is the practical men, technologists and experts who are best equipped to regulate development of mineral wealth now lying dormant within the boundaries of the Empire. Indirectly such men are already furthering this object, both in an advisory capacity and by their contributions to magazines such as this. Several articles follow in illustration of the importance of mineral wealth. Mr. W. G. Boden writes of Canadian radium, showing how important it has become in the fight against cancer. Mr. L. Sanderson describes the rare metal niobium found in association with columbite and which is destined to play an important part in steel stabilisation and welded construction for service in the embrittling zone of temperatures. In addition there are descriptions of the mineral wealth of East Africa, Southern Rhodesia and the Gold Coast. Publicity of this character obviously furthers the case for utilization of British resources to meet British demands.

Distribution of Insecticide by Shot-Gun

IN a report from Science Service (Washington, D.C.) dated April 25 a patent is announced, and briefly described, embodying the application of insecticides by means of shells discharged from a kind of gun. The idea is an American invention, which claims that shot-gun shells can be loaded with compressed wads of insecticide instead of lead shot. When such a shell is fired, the force of the explosion ejects a wad like a bullet, and when it has travelled a certain distance, it breaks down into a cloud of ultra-fine dust. The distance at which the dissolution of the wad will occur depends upon its make-up—its compactness and moisture content. This distance, it is claimed, can be calculated so that the dust cloud can be discharged on a desired tree or crop. The advantages of the method, as claimed by the inventor, are safety of the operator from the effects of a toxic dust; elimination of cumbersome and explosive spray or dusting equipment; practically no labour; and effective distribution of an insecticide in otherwise inaccessible places.

Biochemical Research at the Franklin Institute

WE have received the third volume (1934–35) of "Reports of the Biochemical Research Foundation of the Franklin Institute". In a foreword, the director, Dr. Ellice McDonald, points out that this issue marks the withdrawal of the Cancer Research Laboratories of the Graduate School of Medicine from the University of Pennsylvania and their inception as the Biochemical Research Foundation of the Franklin Institute. The ostensible reason for this withdrawal is the refusal of the University to allow patenting of medical or biochemical discoveries for the continued furtherance of research activities, though not for personal profit. The Institute has decided that the past research done on the cancer problem should be made an avenue of approach to the more general area of other diseases. The objects of the new Foundation are the study of the processes of disease from a chemical point of view, the study of new organic chemical compounds for their therapeutic value and the study of longevity and the diseases of age, with the hope of prolonging the span of life. The present volume contains reprints of some thirty papers published by the staff of the Institute and the Cancer Research Laboratories and their colleagues, dealing in general with various aspects of both normal and abnormal tissue metabolism.

Business Mental Activity and Management

MR. W. R. DUNLOP, of 57 Gordon Square, London, W.C.1, who for a number of years has been interested in the study of business mental activity from the point of view of management and administration, and with particular reference to the logic and probability of decisions, desires to get into touch with a logician with a taste for probability arguments and a psychologist interested in the underlying psychological factors. It is desired, if possible, to arrange a private meeting for joint discussion at which an experienced business manager with introspective ability would also be present. The object would be to get a combined opinion on Mr. Dunlop's method and to make proposals for further studies and investigation. Mr. Dunlop would be greatly obliged if any reader would assist him in getting into touch with specialists willing and competent to collaborate in the direction indicated.

Thomas Gray Memorial Trust

THE Royal Society of Arts, through the Thomas Gray Memorial Trust, the objects of which are "the advancement of the Science of Navigation and the Scientific and Educational interests of the British Mercantile Marine", is offering the following prizes for competition in 1936: a prize of £100 to any person who may bring to their notice an invention, publication, diagram, etc., which is considered to be an advancement in the science or practice of navigation, proposed or invented by himself in the period January 1, 1931–December 31, 1936; a prize of £100 for an essay on the following subject: "What are your views as to the effectiveness or otherwise of Part II. of the Merchant Shipping (Safety and Load Line Conventions) Act, 1932, with special reference to vessels engaged in the carriage of oil and timber cargoes, and with particular regard to actual sea experience?" Further information can be obtained from the Secretary, Royal Society of Arts, John Street, Adelphi, W.C.2.

International Association for Quaternary Studies

THE Association internationale pour l'Étude du Quaternaire européen, which met last at Leningrad in 1932, will hold its third session at Vienna on September 1–5. Prof. A. Penck is honorary president, Prof. G. Götzinger is president and Dr. O. Ampferer is president of the Organizing Committee. On this occasion, however, in accordance with a resolution passed at Leningrad, the scope of the Congress is to be the Quaternary in general and not the Quaternary of Europe only. Communications have already been promised on questions previously arranged for discussion in relation to the Quaternary of Austria and the Alpine glaciations covering stratigraphy, chronology, morphology, climate, prehistory and speleology. MM. Menghin, Kyrle, Beninger and Liebus will devote attention to the palæolithic period. Arrangements have been made for two excursions while the Congress is in session. Of these, one will visit the loess regions of the Danube Valley (Gottweig, Krems) and the other those in the neighbourhood of Vienna (Laaerbeg). At the close there will be a one-day excursion to the Drachenhöhle of Mixnits, while on September 7–8 an excursion will visit the loess of Weinviertel. Finally, a long excursion has been arranged for September 9–25, to visit the Austrian Alps and adjacent terrain. An illustrated guide-book is in course of preparation. Membership is a condition of attendance at the Congress, the annual subscription being 10 schillings (Austrian) or two dollars. In addition to the privilege of attendance at the Congress, members receive copies of reports which cover the progress of quaternary studies from 1908 until 1935. There are at present 180 members of the Congress drawn from twenty-five nations. Communications relating to the Congress or to membership should be addressed to Drs. Götzinger and Ampferer, Geologische Bundesanstalt, Rasumofskygasse, Wien III, or to the General Secretary, Herr H. Gams, Botanische Institut, Innsbruck-Hötting.

Announcements

It is announced that the Right Hon. Viscount Hailsham, the Lord Chancellor, has accepted the chairmanship of the British Empire Cancer Campaign.

At the meeting of the Paris Academy of Sciences on May 25, Paul Portier was elected a member of the Section of Medicine and Surgery, in succession to the late Charles Richet.

Dr. H. J. Plenderleith, of the British Museum Research Laboratory, has been appointed professor of chemistry at the Royal Academy in succession to Dr. A. P. Laurie, whose term of office has expired. The professor of chemistry gives six lectures at the Royal Academy, in October and November. They are primarily intended for the Royal Academy students, but are open free to students of other art schools and Royal Academy exhibitors of the year who may wish to attend.

The Council of the Royal Meteorological Society has awarded the Howard Prize for 1936 to Cadet John Burton Davies, of H.M.S. *Worcester*. The subject of the competition was an essay on "The Causes of Fog over the Open Sea and in Coastal Waters".

We much regret that the name of Prof. A. C. Seward, who is retiring from the chair of botany in the University of Cambridge which he has held since 1906, was inadvertently omitted from the list in Nature of June 27, p. 1063, of those on whom the honour of knighthood has been conferred.

On the occasion of the Congress of Psychiatry held at Rome on April 3, a bust of the neurologist and psychologist, Prof. Sancte de Santis, was unveiled by Prof. Ponzo.

Dr. Marshall C. Balfour, representative in Greece of the International Health Board of the Rockefeller Foundation, has been awarded the silver medal for distinguished services by the Greek Academy of Sciences, Arts and Letters in recognition of his researches on malaria control in the Peloponnese and Macedonia.

The eleventh International Congress of Psychology will be held at Madrid on September 6–12 under the patronage of the Spanish Republic and the presidency of Prof. E. Mira of Barcelona. The official languages will be Spanish, English, French, German and Italian. Further information can be obtained from the general secretary, Dr. José German, Instituto Nacional de Psicotecnica, Alberto Aguilera 25, Madrid.

Applications are invited for the following appointments, on or before the dates mentioned:

A lecturer in anatomy in the University of Birmingham—The Secretary (July 7).

A scientific officer (physics or engineering) in a Government establishment in the south of England—The Secretary, Royal Engineer Board, Regent's Park Barracks, Albany Street, London, N.W.1 (July 7).

A technical assistant (male) in the Air Defence Experimental Establishment, Biggin Hill, Kent—The Superintendent (July 7).

A lecturer in production engineering in the County Technical College, Wednesbury—The Director of Education, County Education Offices, Stafford (July 9).

An assistant lecturer in civil engineering in the City and Guilds College, Imperial College of Science and Technology, Prince Consort Road, South Kensington, S.W.7—The Secretary (July 10).

Chemists (male) at the War Department Chemist, Woolwich Arsenal—The Under-Secretary of State (C.5), The War Office, London, S.W.1 (July 10).

A lecturer in mechanical engineering in the Heanor Mining and Technical School—The Director of Education, County Education Office, St. Mary's Gate, Derby (July 11).

Two assistants (Grade I), one assistant (Grade II) and two junior assistants in the Directorate of Explosives Research; and an assistant (Grade II) in the Directorate of Metallurgical Research in the Research Department, Royal Arsenal, Woolwich—The Chief Superintendent (July 11).

A lecturer in mathematics in the University of Aberdeen—The Secretary (July 17).

A lecturer in physiology in the University of Birmingham—The Secretary (July 17).

A demonstrator in human physiology in the University of Manchester—The Registrar (July 18).

A professor of social anthropology in the University of Oxford—The Registrar.

University College of Science PHYSICS Dept
92, Upper Circular Rd. Calcutta

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 39.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Correlation between Scattering and Recoil in the Compton Effect

As is well known, the experiments of Bothe and Geiger[1] and of Compton and Simon[2] on the correlation between scattering of individual X-ray quanta and electron recoil gave results in complete agreement with the theoretical explanation of the Compton effect, based on the conservation of energy and momentum in each scattering process. The entirely negative results of the recent attempt by Shankland[3] to find such a correlation in the scattering of γ-rays from radium was therefore most unexpected, and it seems desirable to repeat the experiments under conditions as well defined as possible and especially using the much more homogeneous γ-rays from thorium[4].

For this purpose, experiments have been carried out, using a source of 10 mgm. of RaTh filtered by 0·5 cm. lead. The γ-rays next passed through a hole of cross-section 1 — × 1·5 cm. in a lead block 30 cm. thick. The scattering angle was 30° both for the electrons and the quanta, the scatterer was a sheet of paraffin wax of 0·05 cm. thickness. A single counter was used for the detection of the scattered quanta and one for the electrons; the two counters were identical except that the electron counter had an aluminium window with thickness 0·04 mm. and diameter 2 cm. The distance from the counter to the scatterer was about 8 cm.

In a single experiment the coincidences were counted together with the kicks in each of the counters. To determine the number of chance coincidences a lead sheet of thickness 2 mm. was placed in front of the β-counter; the reduction in the number of single kicks caused by the presence of the lead plate was counterbalanced by placing a weak source of RaD close to the electron counter. The number of kicks in the γ-counter was not changed by this procedure. The coincidences found with the lead plate in position give the number of chance coincidences in the first experiment. The following results were obtained in two different series of experiments:

	Kicks per minute				Coincidences per hour		
	Without scatterer		With scatterer		Total (without lead plate)	Chance (with lead plate)	Difference
	β	γ	β	γ			
I	120	28	195	29	6·5 ± 0 6	2·3 ± 0·3	4·2
II	120	120	195	121	11·7 ± 0 9	8·6 ± 0·7	3·1

In the second experiment the number of chance coincidences was increased by exposing the γ-counter to a weak source of RaD. The experiments show that coincidences exist between the β- and the γ-counter in a number which is well beyond the experimental error.

The number of kicks in the γ-counter due to the presence of the scatterer was 1·0 per minute. This was found by replacing the scatterer by a block of paraffin wax of known weight, the proportionality between the weight of the scatterer and the number of kicks being tested by separate measurements. If for each scattered quantum recorded by the γ-counter the corresponding electron was recorded by the β-counter, the number of coincidences would thus be 1·0 per minute. This is, however, reduced considerably by a number of circumstances, such as lack of homogeneity of the primary radiation, scattering within the scatterer, etc., which are difficult to take into account accurately. A rough estimate gives for the expected number of coincidences about 8 per hour, in substantial agreement with the value actually found.

These experiments would, therefore, seem to confirm the usual theory of the Compton effect in every respect.

J. C. JACOBSEN.

[4] Since the experiments recorded above were finished, an account of similar experiments leading to the same results has been published by Bothe and Maier-Leibnitz (*Göttingen Nachr.*, 10, 127; 1936)

Conservation Laws in Quantum Theory

IN connexion with the new experiments on the correlation between scattering and recoil in the Compton effect by Bothe and Maier-Leibnitz, as well as those by Dr. Jacobsen recorded above, both contradicting the conclusions regarding the absence of such a correlation arrived at by Shankland, I should like to make the following brief comments upon the renewed discussion[1] on a possible failure of the laws of conservation of energy and momentum in atomic phenomena, to which Shankland's experiments have given rise.

When in an early attempt[2] at a generalisation of the classical radiation theory suited to meet the puzzling dilemma of the wave and corpuscular character of radiation, doubts were expressed regarding the validity of the conservation laws for individual quantum processes, the situation was quite different from what it is to-day. Not only have subsequent experimental discoveries made us familiar with similar paradoxes regarding the behaviour of electrons and other material particles, but above all has the establishment of rational methods of quantum mechanics and electrodynamics proved the compatibility of the existence of the quantum of action with the strict validity of the conservation laws in all such phenomena as electron diffraction and Compton effect. Moreover, the examination, initiated by Heisenberg, of the complementary limitations in quantum theory of measurements of mechanical quantities as well as of electromagnetic field components[3] has completely removed every paradox in this respect. The essence of the argument may be said to be that any attempt at an unambiguous space-time co-ordination in quantum phenomena implies a renunciation of the strict application of the conservation laws, due to the essentially uncontrollable exchange of energy and momentum between the object under investigation and the rigid bodies and clocks which define the space-time frame; conversely, any well-defined application of the conservation laws in quantum phenomena implies an essential renunciation as regards space-time co-ordination[4].

As the fundamental relations between the wave and particle aspects of light and matter can be expressed in full conformity with the relativity principle, the still unsolved difficulties of quantum electrodynamics, emphasised by Dirac in connexion with this discussion, can scarcely be attributed to any incompatibility between the foundations of quantum theory and relativity theory. The root of these difficulties may rather be looked for in the atomistic nature of electricity, which is as foreign to classical physical theories as the quantum of action itself. The rational incorporation of these different aspects of atomic problems in a comprehensive theory will probably claim entirely new points of view, taking the essentially atomistic structure of all measuring agencies into consideration; but at the moment there would seem to be no reason to expect that this would involve any real departure from the conservation laws of energy and momentum.

Finally, it may be remarked that the grounds for serious doubts[5] as regards the strict validity of the conservation laws in the problem of the emission of β-rays from atomic nuclei are now largely removed by the suggestive agreement between the rapidly increasing experimental evidence regarding β-ray phenomena and the consequences of the neutrino hypothesis of Pauli so remarkably developed in Fermi's theory.

$[SO_3]_x$

MESSRS. Gerding, Nijveld and Muller[1] infer from the Raman spectrum of sulphur trioxide that it is a mixture of polymorphs. It is interesting to have such information, but to chemists who have known the compound this has always been a necessary assumption.

I remember Frankland introducing me to sulphuric anhydride early in 1867, at the Royal Institution, where we were doing gas analysis with the Frankland and Ward apparatus. He distilled it out of Nordhausen acid, using a bulb blown on the spot from an odd bit of tube, heating the small still on a warm tile of a Hofmann combustion furnace. To-day I can see him doing this: it was the way he had of showing one how to use one's fingers. Somehow I fell in love with the silken beauty of the oxide. As a German student, it was my first research *Schatz*: I cultivated its more acquaintance by the kilo, to the surprise of my fellow students and even of Kolbe.

I am carried back to 1868, when I tested its action on a large number of chlorides. Typical is the effect it has on carbon tetrachloride, forming carbonyl chloride and pyrosulphuryl chloride, $S_2O_5Cl_2$, it would seem directly, as SO_2Cl_2 and SO_3 do not combine. On the other hand, the anhydride combines readily with HCl and EtCl forming simple chlorides—compounds which behave, however, as though they were the trioxide: they are not active apparently through their chlorine, as indeed is the case with acid chlorides generally. Pyrosulphonyl chloride is both a sulphonating and a chlorinating agent; sulphonyl chloride chlorinates.

The peculiarities of the 'trioxide' are not sufficiently recognized. It has high residual affinity. It is the perfect sulphonating agent, used alone but preferably diluted with sand. SO_2HCl is a convenient form in which to administer it—not nearly so powerful; the anhydride may even be used in solution in SO_2HCl with effect. I always feel proud of having introduced this chloride into use; it has played a big part in the manufacture of saccharin.

No text-book does justice to the protean character of the sulphuric acids: their properties have been Ostwaldized into oblivion. $\frac{1}{2}H_2SO_4$ is not the equivalent of the acid: it is 90 per cent a monosulphonic acid—the lactic acid of the sulphur series—not dihydric sulphate. The well-defined stable acid of the series is anhydrosulphuric acid—*oxodisulphonic acid*. The first product of the interaction of vitrolic acid and, say, salt or sodium nitrate is not the acid sulphate of the text-books but $H_3Na(SO_4)_2$—a fact which makes the use of nitre in nitrations uneconomic. When chemists some day recover the full use of symbols and pay attention to facts, these and not a few other matters will receive the attention too long denied to them. Sulphonation is the most important of all the processes in the dyestuff industry—and we owe it to Faraday.

Kinetics of Gas Reactions: an Attempt to Connect Thermal Decomposition and Oxidation Processes

THE thermal decomposition of formaldehyde[1] and of acetaldehyde[2] can be represented by $x-t$ graphs which indicate a period of rapid decomposition, followed by one of slow decomposition. The experimental results of Spence[3] for the rates of oxidation of formaldehyde appear to be represented by similar graphs, indicating a similarity in the processes. Seddon and I have pointed out[4] that, in the case of acetaldehyde, the total rate of thermal decomposition appeared to be independent of all conditions except temperature and initial concentration, the nature of the final products, whether methane and carbon monoxide on one hand, or propylene, carbon dioxide and water on the other, being materially dependent on certain other conditions.

Now in the case of the oxidation of formaldehyde, it appears that the final stage in the process follows two alternative courses, which may be represented by,

$$(CH_2O_2)\begin{array}{l}\nearrow CO_2 + H_2\\ \qquad\text{or}\\ \searrow CO + H_2O.\end{array}$$

Spence refers to the penultimate stage as involving the formation of "activated formic acid", but it is perhaps wise to avoid the nomenclature of organic chemistry, and speak of a "short-lived intermediate" of composition (CH_2O_2).

One may imagine that the system passes through a series of states defined by symbols X, X_1 . . . X_x . . . $X_{(n-2)}$, $X_{(n-1)}$, X_n. To account for the similarity between oxidation and thermal decomposition processes, it seems to be necessary to assume that there is some change which is dominant and common to both, and I suggest that this is to be found in the transition represented by,

$$X_{(n-2)} \rightarrow X_{(n-1)}.$$

This is the change involved in the formation of the short-lived intermediates. The probability of reversal of this process is, as Seddon and I suggest, small, and the energy drop considerable. The energy is utilized in a process represented by,

$$X \rightarrow X_1,$$

that is, in increasing the probability of the formation of new primary centres.

The suggestion is somewhat similar to one of those put forward by Semenoff. Qualitatively, it would involve the initial acceleration of the process, which would afterwards slow down. In a considerable number of processes, involving relatively small energy changes, which have been investigated in this laboratory by means of detailed analyses, the form of the $x-t$ graphs is very similar, showing a very sudden transition from rapid to slow reaction generally at or before 50 per cent change. This seems to happen in the case of the oxidation of formaldehyde and in the thermal decomposition of acetaldehyde.

Vitamin P: Flavonols as Vitamins

VARIOUS chemical and clinical observations have led to the assumption that ascorbic acid is accompanied in the cell by a substance of similar importance and related activity. In absence of both substances, the symptoms of lack of ascorbic acid (scurvy) prevail and conceal symptoms of the deficiency of the second substance. In the lack of suitable experimental animals or conditions, progress was dependent on spontaneous pathological conditions, caused or influenced by this second factor.

In collaboration with L. Armentano and A. Bensáth, we have found that in certain pathological conditions, characterised by an increased permeability or fragility of the capillary wall, ascorbic acid is ineffective, while the condition can readily be cured by the administration of extracts of Hungarian red pepper ('vitapric') or lemon juice. The extracts were effective in cases of decreased resistance of the capillary wall toward whole blood (vascular type of hæmorrhagic purpura) as well as in cases in which the capillary wall showed an increased permeability towards plasma protein only (various septic conditions). The extracts were fractionated. The active substance was found in the end in a fraction consisting of practically pure flavon or flavonol glycoside. 40 mgm. of this fraction given daily intravenously to man restored in a fortnight regularly the normal capillary resistance. Spontaneous bleeding ceased, the capillary walls lost their fragility towards pressure differences and no more plasma protein left the vascular system on increased venous pressure.

These results suggest that this great group of vegetable dyes, the flavons or flavonols, also play an important role in animal life, and that the dyes are of vitamin nature. The group is not to be confused with the yellow dye, discovered by one of us and termed 'flaves' (like cytoflave), which dye forms the prosthetic group of Warburg's yellow enzyme and has later been renamed by R. Kuhn 'flavins'. We propose to give the name 'vitamin P' to the substance responsible for the action on vascular permeability.

Role of Adenylic Acid in Vitamin B_1 Deficiency

THE work of Peters[1] and his collaborators has shown that abnormal amounts of lactic and pyruvic acid accumulate in the brain of the polyneuritic pigeon. Further evidence of the Oxford school has demonstrated that the brain tissue of such polyneuritic pigeons exhibits a lowered oxygen consumption in the presence of either pyruvic or lactic acid. The addition of vitamin B_1 *in vitro* to such tissue restores the oxygen uptake to a large extent. Other workers[2] have also pointed out the presence of excessive amounts of lactic acid in the tissues of the vitamin B_1 deficient animal. This emphasis on the 'lactic acid' theory of the vitamin B_1 syndrome led Drury, Harris and Maudsley[3] to suggest that the bradycardia found by them in vitamin B_1 deficient rats was due to the excessive accumulation of lactic acid in the heart. No direct evidence was brought forward to support this theory, although the results of Birch and Harris[4] showed that the severity of the bradycardia went parallel with the lactic acid level in the blood.

The attention which has been devoted to this theory has obscured the similarity between the effect of adenine nucleotides on the normal heart and the effect of vitamin B_1 deficiency on this organ. In the rat, the bradycardia produced by certain adenine compounds apparently resembles in all respects that produced by avitaminosis B_1. For example, with moderate avitaminosis or with small doses of adenylic acid, the heart exhibits a simple slowing. In severe avitaminosis when the heart rate is below 350 beats per minute the auricular wave disappears[3]. This disappearance of the auricular wave also occurs when a large enough dose of adenylic acid is injected.

These facts have led us to study the action of adenine nucleotides on the heart of both the normal and vitamin B_1 deficient animal.

It was found possible to increase further the bradycardia already present, due to vitamin B_1 deficiency, by the injection of small amounts of adenosine, or either of the adenylic acids from muscle or yeast. Using normal animals, a much smaller effect was obtained with the same dosage of these substances. The results using muscle adenylic acid are shown in Fig. 1.

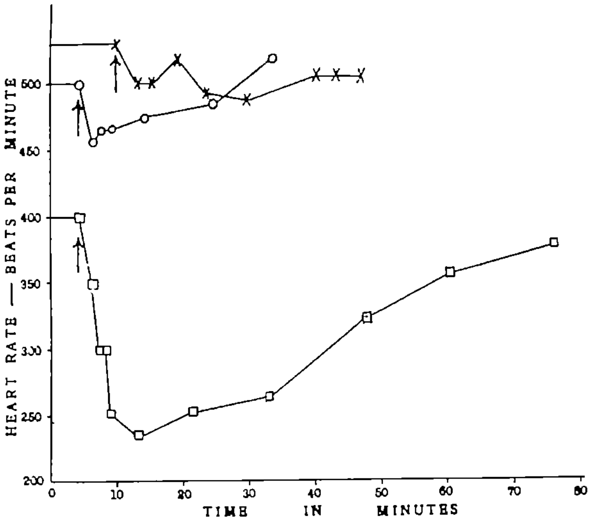

FIG. 1. Effect of muscle adenylic acid on heart rate. 3 mgm. of the acid were injected at points marked by the arrows. □, Vitamin B_1 deficient animal; ×, same animal 18 hours after administration of vitamin B_1; ⊙, animal on 'stock diet'.

These experiments demonstrate that the vitamin B_1 deficient animal is more sensitive to the action of these compounds. This increased sensitivity disappears completely 18 hours after the administration of vitamin B_1, the heart rate having by this time returned to its normal value.

These results suggest that the B_1 deficient animal is unable to render these compounds innocuous at the same rate as does the normal animal.

The two known mechanisms whereby the adenylic acids are converted into substances having little or no effect on cardiac muscle are (1) deamination to ammonia and inosinic acid; (2) phosphorylation to adenosine di- or tri-phosphate.

We have as yet studied only the first of these mechanisms, and have established the fact that the deaminase activity of vitamin B_1 deficient cardiac tissue is on the average more than 20 per cent lower than similar tissues from control animals on a full 'stock diet'. Moreover, tissue obtained from cured animals 18 hours after administration of the vitamin shows a deaminase activity equal to that of normal animals.

Ammonia Produced in 40 minutes per gram of Heart Tissue

	Normal		B_1 deficient
	1,010 γ		778 γ
	998 ,,		710 ,,
	1,041 ,,		752 ,,
	987 ,,		807 ,,
	918 ,,		955 ,,
	875 ,,		695 ,,
	995 ,,		725 ..
	1,072 ,,		845 ,,
Average	982 ,,	Average	783 ,,

We have not yet succeeded in obtaining this restoration of deaminase activity by the direct addition of vitamin B_1 to deficient tissue *in vitro*. This fact, as well as the delayed recovery in the heart rate after administration of vitamin B_1, may indicate that in the rat the vitamin must first be synthesised into another compound before its biological action is manifest.

It seems possible that this failure of the deaminase mechanism may result in an increased accumulation of adenylic acid in the tissue, which is the cause of the bradycardia. Likewise, many of the effects obtained with vitamin B_1 deficient tissues (for example, increased lactic acid and decreased oxygen consumption) may be due to the inhibition by adenylic acid of the oxidative mechanisms which are responsible for the removal of these metabolytes.

Equivalent Particle-Observers

MILNE[1] and Page[2] have attempted to build up relativistic theories without employing the concepts of *rigid body* or *absolute clock*. Now we can certainly abandon one of these concepts. The possibility of getting rid of the rigid body (assuming an absolute clock) was pointed out by me some time ago[3], while (assuming rigid bodies) we can avoid the absolute undefined clock by employing a light ray oscillating between mirrors at the end of a rigid rod. But to proceed with *neither* concept, as Milne and Page appear to do, is not possible.

Basic in the theories of Milne and Page is the concept of *equivalent particle-observers*. A *particle-observer* is simply a particle equipped with a clock, not an absolute clock, of course, but just any clock that assigns a monotonically increasing sequence of numbers to the events that occur at the particle. According to Milne (*loc. cit.*, p. 30) two particle-observers are *equivalent* if their clocks can be so regulated that, on exchange of light signals between them, there exist certain relations between times of departure and reception of the signals. Page (*loc. cit.*, p. 256) states that in similar circumstances the *clocks* are equivalent, "or that the two particle-observers are equivalent".

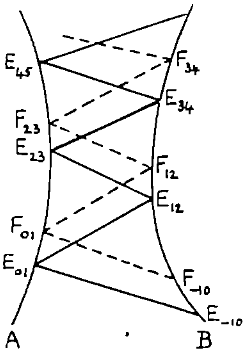

FIG. 1.

This idea of equivalence, at least so far as just two particle-observers are concerned, seems quite a hollow one, because (as will be shown below) *any two particle-observers are equivalent*. Further, the statement that two particles have a *constant relative velocity* is devoid of any absolute physical meaning in terms of the definitions employed (provided that we think only of two particles), because it is always possible by proper choice of 'equivalent' clocks to make this velocity zero.

Consider the world-lines of two particle-observers A, B (Fig. 1). Starting with any event E_{01} in the history of A, we may construct a 'ladder' by means of a light ray passing to and fro between A and B, the 'corners' of the ladder being the events . . . E_{-10},

E_{01}, E_{12}, E_{23}, . . . as shown. Let us choose any positive number k and assign to the events of A between E_{01} and E_{23} a time parameter t, arbitrary except for the conditions that it shall increase monotonically from $t=0$ at E_{01} to $t=2k$ at E_{23}. Let F_{01} be any event in the interval (E_{01}, E_{23}) and let its time be t. Let us construct the ladder having F_{01} for a corner and let us assign to the events at the corners of this ladder (both on A and on B) values of t such that

$$t(F_{n,n+1})=t(F_{n-1,n})+k, \quad (n=\ldots-1,\,0,\,1,\,2,\ldots).$$

Letting F_{01} range over (E_{01}, E_{23}), we assign by this process a value of t to every event in the histories of both particles, the assignment of t over (E_{01}, E_{23}) remaining arbitrary except for the terminal values (0, $2k$).

The time-systems assigned as above satisfy the conditions of equivalence of Milne and Page. Thus any two particles are equivalent. Incidentally, on account of the arbitrary choice of t in (E_{01}, E_{23}) it is obvious that the following statement of Page is not true (*loc. cit.*, p. 257): "The readings of the clocks of P and P' are fixed to within an arbitrary additive constant by the condition that they be equivalent." Furthermore, the 'distance' of Milne and Page between the two particles is constant for equivalent clocks defined as above. Their 'relative velocity' is zero.

It would seem that both Milne and Page have permitted their partially arbitrary clocks to assume an absolute significance. It must be understood, however, that the above remarks apply only to a system of two particles. With more particles the question of equivalence may take on more physical reality.

Time Effects in Supra-conductors

IN continuation of previous investigations on the magnetic hysteresis phenomena in supraconductors, we have recently reported on experiments concerning the time effect[1]. We observed that after a sudden change of one of the variables of state (magnetic induction or temperature), a final value of the induction in a long supra-conducting cylinder was only attained after a considerable time (up to 20 minutes). The effect was strongest in single crystals and very pure polycrystalline specimens.

As a possible explanation, we tentatively suggested that the redistribution of supraconductive and normal material was perhaps delayed by the slow dying-out of induced currents in the boundary surface between the two states. Such an explanation necessitates, of course, the existence of macroscopic supra-conductive and normal regions in the specimen. It has been recently worked out by R. Peierls[2] and F. London[3] independently (we are much indebted to both authors for giving us an opportunity to acquaint ourselves with the theories before publication, and for the permission to quote their results), that the existence of such macroscopic regions is unlikely in a sphere, whereas the assumption of such a region seems to us necessary in a body of a more complicated form, for example, a short cylinder.

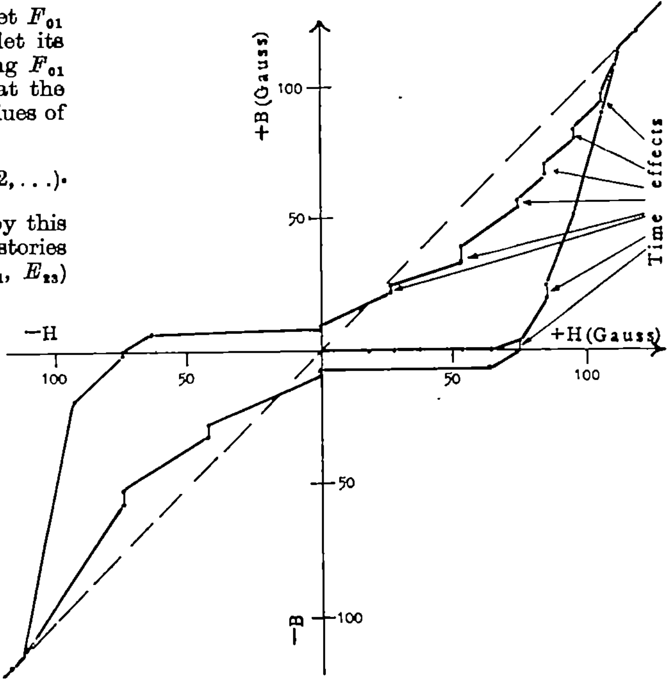

FIG. 1. *B/H* curve of short cylinder of polycrystalline tin, temperature constant, 2·842° K.

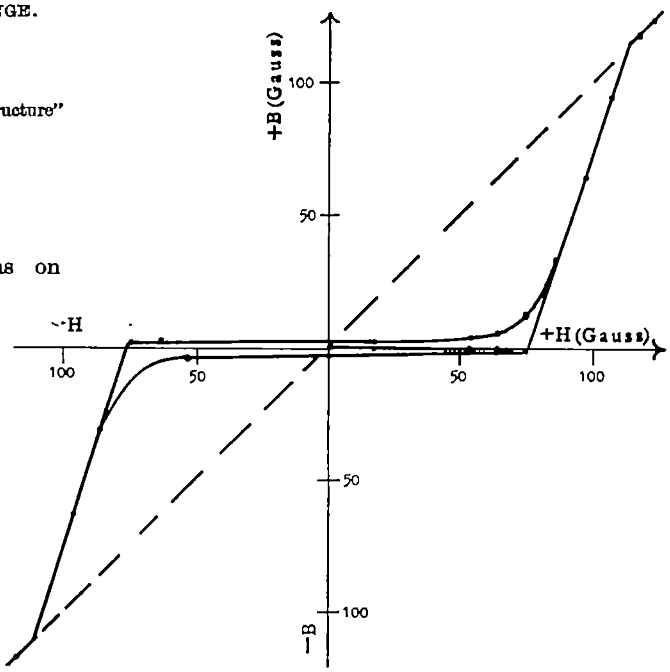

FIG. 2. *B/H* curve of sphere made from cylinder of Fig. 1, temperature constant, 2·85° K.

We have therefore determined the relation of the induction (B) to the external field (H) in a short cylinder of very pure polycrystalline tin. The result is given in Fig. 1, and it can be seen that when the external field is altered, it takes in many cases an appreciable time before a final value of the induction is reached.

After this experiment, the cylinder was worked down carefully to the shape of a sphere. The change of induction observed now (Fig. 2) is nearly reversible, and no time effects were observed.

In both experiments, the first determination of the induction was carried out about 10–15 seconds after the field had been changed. In the second experiment, no variation of induction was observed after this time, whereas a variation was observed even after 3–4 minutes in the first case.

The results show clearly that in the same sample time effects may or may not occur, and that their occurrence depends on the geometrical form of the specimen. Considering the facts stated above, the experiments seem to confirm our assumption that the time effects indicate a slow expansion or contraction of macroscopic supra-conductive regions.

Determination of Physico-Chemical Constants

THE high sensitivity of W. Swietosławski's ebulliometric test of the purity of liquid substances[1] permits the correlation of data for any physico-chemical property with Δt, the difference between the boiling point and condensation temperature of the substance under investigation, in order to calculate the constants for the pure substance or azeotropic mixture.

The difference mentioned, Δt, when measured in an ebulliometer of standardised dimensions, is a criterion of purity of liquid substances, and for a pure substance it equals zero. Having made measurements of Δt and of a given constant for a series of preparations of the same compound having different degrees of purity, as for example a few successive fractions of distillate from an efficient column, one may plot Δt, the difference between the boiling point and temperature of condensation of each of the preparations, against the data obtained for the given constant. Direct extrapolation of the curve to the point where Δt equals zero gives the constant corresponding to the pure substance or azeotropic mixture.

The determination of the boiling point of iso-amyl alcohol by W. Swietosławski's comparative method[2] may serve as one example of such a correlation. In Table 1 there are listed: number of the fraction, the difference Δt, the degree of purity on W. Swietosławski's scale[1], and the normal boiling point of each of the samples investigated.

Table 1.

No.	Δt	d.p.	b.p.
1	0 032	III	131·067
2	0 019	IV	131·450
3	0 005	V	131·779
4	0·002	V	131·802

The boiling point of pure iso-amyl alcohol obtained by extrapolation of these data is 131·806° C.

The precise determination of density by means of the twin pycnometer method[3] furnishes another example of measurements which may be correlated with Δt to obtain the densities of pure liquids. In Table 2 the densities of two fractions of n-propyl acetate are given, together with the corresponding values of Δt and degree of purity. The density of pure n-propyl acetate obtained by extrapolation to $\Delta t = 0$ is $0{\cdot}88299_3$ gm./cm.^{3} at 25° C.

Table 2.

Δt	d.p.	d(gm./cm.^{3} at 25° C)
0·011	IV	0 882832
0 004	V	0·882939

It is worth noting that as the degree of purity of the substance investigated becomes higher, the change in the property measured becomes more nearly linear with Δt, thus permitting a reliable extrapolation to $\Delta t = 0$. Details will be published elsewhere.

Metabolism of Cartilage

IT has been found by means of Warburg's manometric method that the metabolism of cartilage is entirely anærobic; it splits glucose to form lactic acid at a rate of about 0·2 c.mm. carbon dioxide (produced from bicarbonate solution) per mgm. dry weight per hour, that is, about a tenth the rate of nearly related connective tissues forming the synovial villi, and a fiftieth the rate of the choroid plexus[1]. By means of cell counts and corrections for specific gravity and drying, it has been shown that this glycolysis is essentially of the same order per cell as in most other adult tissues. This glycolysis is the

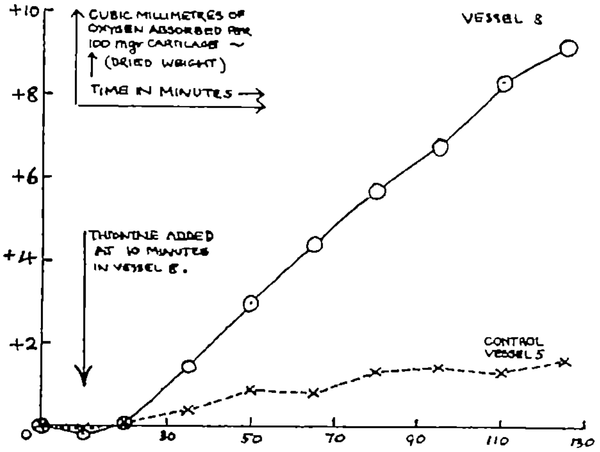

FIG. 1. Diagram showing oxygen uptake of cartilage with addition of dyestuff.

same whether measured under ærobic or anærobic conditions. Rabbit cartilage was kept for a fortnight under aseptic anærobic conditions in bicarbonate Ringer solution with glucose, and its glycolysis measured throughout. At the end of the experiment it had only fallen to 0·09 from an initial $Q_{CO_2}^{N_2}$ (c.mm. carbon dioxide per mgm. dry weight per hour in nitrogen) of 0·34.

There is no oxygen uptake that can be measured certainly by this method; if it exists, the Q_{O_2} (c.mm. oxygen consumed per mgm. dry weight per hour) must be at most 0·01, and probably below 0·005. With methylene blue, however, an immediate large increase in oxygen uptake occurs, paralleled only by the similar behaviour described by Harrop and Barron[2] of non-nucleated mammalian red corpuscles. The Q_{O_2} rises from an average of −0·003 (nine experiments) before, to an average, using the same slices, after addition of dye, of −0·065—a twenty-fold increase.

Oxide Layer on a Polished Copper Surface

THE application of electron diffraction to the problem of the structure of polished metal surfaces has greatly extended the knowledge gained from microscopical methods. In general, in the course of polishing, the rings of the electron diffraction pattern become blurred until they run into two broad haloes. As these changes may be explained by assuming that the metal crystals become smaller and smaller as the polishing progresses, the above-mentioned results are strongly in favour of Beilby's supposition that the topmost layer of highly polished metal is amorphous[1].

There is, however, considerable difficulty in accounting for the fact that the haloes have been found to be practically the same for all metals. They correspond to the spacings 2·25 A., and 1·28 A. ± 5 per cent respectively. This apparent uniformity could scarcely be expected. If we assume the polish layer to be composed of very small crystals, the radius of the haloes should depend on the lattice constants, while if the layer be completely amorphous it would be the atomic volume which should govern their size.

As the majority of the metals investigated are known to be easily oxidisable, it was decided to examine how far these difficulties might be due to the formation of an oxide film on the surface in the course of polishing. After having obtained results concordant with those of other authors for copper polished in the usual way with wet rouge, in air, I polished a specimen under the surface of benzene. This gave haloes of quite different size corresponding to spacings of 1·91 A. and 1·16 A. As polishing under pentane yielded the same result, it seemed likely that the pattern commonly attributed to polished copper is actually due to the oxide. To make sure, the specimen which had been polished under benzene was left in the air and the changes in the pattern were traced by taking pictures every few hours. It was possible to follow the gradual decay of the original haloes and gradual appearance of the pattern corresponding to the spacings 2·24 A. and 1·28 A. The last pattern, which is the one obtained after polishing in air, is thus clearly due to an oxide.

Whereas in the pattern obtained in the absence of air the inner halo may be interpreted as the effect of degeneration of the (111) and (200) rings of copper, and the outer one of the (220), (311) and (222) rings, the haloes obtained in air occur exactly in places where one may expect maxima of intensity after blurring of the corresponding rings of cuprous oxide, the cube side of copper being 3·61 A. and of Cu_2O 4·25 A.

Many of the properties of a polished copper surface have recently been found to differ from those of a polycrystalline one[1]. As usually no special precautions against oxidation are observed during polishing, an interesting question arises as to how far these differences are to be attributed to the change of the physical state of the surface, and how far to change of chemical composition.

The investigation is being extended to other metals, as it is known that many metals which have themselves different crystalline structures, such as iron and nickel, have face-centred cubic oxides with a cube-side differing from that of Cu_2O by only a few per cent. This fact may be partly responsible for the apparent uniformity of size of the haloes.

Electrolytes and a General Phenomenon in Tissue Cells

THE starting point of the present experiments was the assumption that the practically undiffusible particles of protoplasm are charged by the *per se* diffusible electrolytes with the formation of a double layer, and are maintained thereby in a dispersed state. If this be the case, then there must exist a certain equilibrium between the electrolytes, which build up the double layer on the particles of the protoplasm, and the electrolytes in the surrounding medium.

It must also be considered that this might concern thermodynamically a Donnan equilibrium—since the latter exists independently of the way in which the diffusible ions are adsorbed on the non-diffusible particles. In this case, if the salt ion contents of the outside liquid are diminished to nearly zero, then all the salt ions, as is well known, travel to the outside liquid.

If the above reasoning is valid, then it must be expected that if one makes the medium outside the tissue cells nearly free from electrolytes, the salt ions will travel to the outside liquid. Consequently a discharge, and a coagulation of the non-diffusible and discharged particles of protoplasm, would be expected.

It has been possible in the case of tissue cells cultivated in liquid media to make the liquid outside the cells nearly free from electrolytes and to produce thereby a discharge (most active Brownian movement in the protoplasm as a sign of a minimum of viscosity; obviously advancing aggregation of the particles of the protoplasm). The following results have been obtained:

(1) If tissue cells are brought from their liquid culture medium, after several washings, into a medium free from electrolytes, then within a few seconds the following phenomena, consisting of three main effects, take place: (*a*) an assumption of globular form by the cells; (*b*) the appearance of a vivid Brownian movement of the granules and vacuoles in the cytoplasm, as a sign of a maximal reduction of the viscosity in consequence of a discharge with simultaneous increasing absorption of water; (*c*) a process of slow coagulation in the cytoplasm, which manifests itself in the appearance of new particles in vivid Brownian movement, which continuously increase in size. The gradual multiplication and increase of the particles is best seen with dark field illumination, but the vivid Brownian movement is also well seen with direct illumination.

(2) In some of the cells which have become globular, there occurs a bursting of the cell, with extrusion of liquid contents containing particles in Brownian movement (analogous to hypotonic hæmolysis with extrusion of hæmoglobin). Sometimes the torn parts adhere together again after diminution of the interior pressure.

(3) The presence of non-electrolytes in the medium ($n/36-n/12$ dextrose: $n/5-n/1$ urea) does not hinder the appearance of the phenomena described, but naturally reduces the activity of the Brownian movement in the cytoplasm.

(4) The phenomena described are reversible. The reversal can be produced after several minutes by means of Ringer solution, $n/10$ sodium chloride, or $n/10$ sodium bromide. The cells regain their former shape extremely quickly, with immediate stoppage of the Brownian movement in the cytoplasm. The cells then show normal vital staining.

(5) The phenomena can only be produced with living and not with dead cells. Failure is a sure sign of cell death.

The results of these experiments prove the justness of the above assumptions. Furthermore, they show that hypotonic hæmolysis is only a special case of a general phenomenon in tissue cells. They reveal, furthermore, a fundamental property of tissue cells in which the salt ions of the tissue liquid participate decisively in the maintenance of the particle charge of the protoplasm.

Anatomical Institute,
Turin.

A Syndrome produced by Diverse Nocuous Agents

EXPERIMENTS on rats show that if the organism is severely damaged by acute non-specific nocuous agents such as exposure to cold, surgical injury, production of spinal shock (transcision of the cord), excessive muscular exercise, or intoxications with sublethal doses of diverse drugs (adrenaline, atropine, morphine, formaldehyde, etc.), a typical syndrome appears, the symptoms of which are independent of the nature of the damaging agent or the pharmacological type of the drug employed, and represent rather a response to damage as such.

This syndrome develops in three stages: during the first stage, 6–48 hours after the initial injury, one observes rapid decrease in size of the thymus, spleen, lymph glands and liver; disappearance of fat tissue; œdema formation, especially in the thymus and loose retroperitoneal connective tissue; accumulation of pleural and peritoneal transudate; loss of muscular tone; fall of body temperature; formation of acute erosions in the digestive tract, particularly in the stomach, small intestine and appendix; loss of cortical lipoids and chromaffin substance from the adrenals; and sometimes hyperæmia of the skin, exophthalmos, increased lachrymation and salivation. In particularly severe cases, focal necrosis of the liver and dense clouding of the crystalline lens are observed.

In the second stage, beginning 48 hours after the injury, the adrenals are greatly enlarged but regain their lipoid granules, while the medullary chromaffin cells show vacuolization; the œdema begins to disappear; numerous basophiles appear in the pituitary; the thyroid shows a tendency towards hyperplasia (more marked in the guinea pig); general body growth ceases and the gonads become atrophic; in lactating animals, milk secretion stops. It would seem that the anterior pituitary ceases production of growth and gonadotropic hormones and prolactin in favour of increased elaboration of thyrotropic and adrenotropic principles, which may be regarded as more urgently needed in such emergencies.

If the treatment be continued with relatively small doses of the drug or relatively slight injuries, the animals will build up such resistance that in the later part of the second stage the appearance and function of their organs returns practically to normal; but with further continued treatment, after a period of one to three months (depending on the severity of the damaging agent), the animals lose their resistance and succumb with symptoms similar to those seen in the first stage, this phase of exhaustion being regarded as the third stage of the syndrome.

We consider the first stage to be the expression of a general alarm of the organism when suddenly confronted with a critical situation, and therefore term it the 'general alarm reaction'. Since the syndrome as a whole seems to represent a generalised effort of the organism to adapt itself to new conditions, it might be termed the 'general adaptation syndrome'. It might be compared to other general defence reactions such as inflammation or the formation of immune bodies. The symptoms of the alarm reaction are very similar to those of histamine toxicosis or of surgical or anaphylactic shock; it is therefore not unlikely that an essential part in the initiation of the syndrome is the liberation of large quantities of histamine or some similar substance, which may be released from the tissues either mechanically in surgical injury, or by other means in other cases. It seems to us that more or less pronounced forms of this three-stage reaction represent the usual response of the organism to stimuli such as temperature changes, drugs, muscular exercise, etc., to which habituation or inurement can occur.

Estimation of Fatty Acids in Organic Mixtures

FOR the determination of the volatile fatty acids in cheese, it is usual to subject the acidified cheese mush to a normal steam distillation at constant volume. In this laboratory, it is the custom to collect a volume of distillate equal to three times the volume of the liquid in the distillation flask, and to use this for further estimations of the individual acids.

The study of the rate of recovery of various volatile acids, added in known quantities to the cheese mush, led to doubt as to whether this method of distillation resulted in the complete extraction of the volatile acids (especially the higher members of the series) from the cheese. It appeared that the higher acids were to some extent held back by the constituents of the cheese, and did not therefore distil over at the rate suggested by Dyer's figures[1].

This view was strengthened by a series of experiments in which several acids were distilled from water, and a mixture of fresh, washed butter fat and water. It was evident that there was retention of some of these acids by the butter fat, very marked for lauric acid and high for caprylic, but decreasing through caproic to butyric and the lower members of the series, in which no retention was demonstrated.

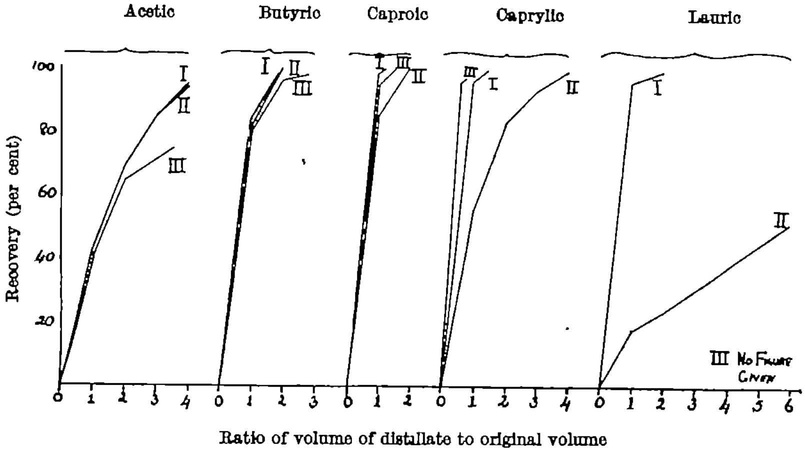

FIG. 1. Fatty acid recovery by steam distillation: I, acid distilled from distilled water; II, acid distilled from pure butter fat; III, distillation figure given by Dyer.

It was found, however, that although the rate of distillation of the higher acids was retarded by the presence of butter fat, almost complete recovery could be effected if the steam distillations were continued for a sufficiently long period. For the acids up to and including caprylic, more than 90 per cent of the added acid could be recovered by collecting a distillate of three times the original volume. For lauric acid, on the other hand, only 50 per cent was recovered even after collecting six times the original volume (cf. Fig. 1).

If the rate of distillation of these acids from a cheese mush is comparable with that from a mixture of butter fat and water, then the practice of collecting a distillate of three times the original volume would allow an estimate of the distribution of volatile acids in cheese which would be sufficiently accurate for many purposes. It is suspected, however, that a still greater retention occurs in the cheese mush, and the influence of cheese fat (as distinct from butter fat) and the protein and salt mixtures of cheese is being examined in an effort to elucidate this question.

The Stock of Antarctic Blue Whales

DURING the current investigations into the conditions of Southern whaling, I have had occasion to consult the publications[1] of the Norwegian Whaling Bureau, in which the catch statistics given in "International Whaling Statistics" have been amplified and to some extent analysed. From these data I have calculated the average length of female Blue whales taken from 1930 to 1935. The results are shown in the following table.

Season	No. of whales considered	Average length (ft.)
1930–31	4,532	82·36
1931–32	close season	— —
1932–33	5,285	81·97
1933–34	6,487	81·85
1934–35	7,253	79·88

A slight annual decrease in length up to 1933–34 is followed by a sharp drop of nearly two feet in 1934–35. Blue females become sexually mature at about 78 ft., when they are approximately two years old. They arrive at maturity in the southern winter, and are found in the Antarctic the following summer with an average length of 80 ft. Pairing in July may result in pregnancy which lasts for ten months[2].

Blue females taken in 1934–35 were, therefore, on the average, killed at the outset of their reproductive career. The consequences of continued intensive killing need scarcely be emphasized.

Average lengths were shown in the Norwegian publications, but the data had been divided, and average lengths were given for immature and adult whales separately. The constancy of the averages from season to season was invoked as evidence that undue depletion of the stock is not yet taking place, but since no account was taken of the rapidly mounting percentage of immature whales in the catch the results are liable to be misleading.

The Manatee of St. Helena

IN NATURE of March 17, 1934, p. 417, Prof. T. Mortensen quotes Dampier's reasons for refusing to believe in the existence of the sea-cow in St. Helena. The bibliography on the subject appears to be far from complete; but fortunately records by two eye-witnesses are available.

Probably the best account of the St. Helena manatee will be found in Barnes's "Tour of St. Helena" (Richardson, London, 1817, pp. 116 and 117), where a detailed description of the animal is quoted from the manuscript of Lieut. Thomas Leech, "written many years ago". The Leechs were a well-known and highly respectable Island family, and Thomas

Leech, who affirmed that the sea-cow was really a sea lion, is mentioned in Brooke's "History of St. Helena" (1824 ed., p. 51), as one "who by his unwearied pursuits in historical research, and his surprisingly retentive memory had acquired a great degree of general information".

There is another very important reference in Dr. Walter Henry's "Events of a Military Life" (2nd ed., Pickering, London, 1843, vol. 2, pp. 66 and 67), which is as follows:

"We had sea-cows at St. Helena, the Trichechus Dugong, but they were not common. When shooting near Buttermilk Point with another officer one calm evening, we stumbled on one lying on a low rock close to the water's edge, and a hideous ugly brute it was, shaped like a large calf, with bright green eyes as big as saucers. We only caught a glimpse of it for a few seconds, for as soon as it noticed us, it jumped into the sea, in the most awkward and sprawling manner."

Dr. Henry, whose book is well known to Napoleonic students, was an alert and accurate observer of current events, who later reached high rank in the Army Medical Service and died in 1860. His observations were made between 1817 and 1821; probably in 1819.

It may be a convenience to students if I recapitulate the references to be found to sea-cows in the Public Records of Jamestown:

1679, January 27.	First use of the name Manatee Bay.
1682, August 28.	Several sea-cows caught.
1690, March 20.	A very small sea-cow killed.
1691, May 11 (a month before Dampier's visit).	Sea-cow on shore to Windward.
1716, August 29.	400 lb. ambergris found in Manatee Bay.
1739, September 11.	A sea-cow killed.

Burnham's sea-cow of 1810 referred to by Lydekker and Mortensen, I am unable to trace as recorded in the Public Records; but the latter quotes Janisch's confirmation of it to be found in "Scraps from Records" (Government Printer, Jamestown, 1880, to accompany the St. Helena Almanack of that year).

A Case of 50 per cent Crossing-over in the Male *Drosophila*

WITH the view of synthesising a double recessive black-vestigial stock of *Drosophila melanogaster*, Dr. G. Eloff[1] made a cross of black and vestigial, both of which are contained in the second chromosome. The F_2 generation, to his surprise, contained many *b vg* flies. To solve the question, the F_1 males were mated with double recessive females (*b vg*), when an independent segregation of black and vestigial was found. He applied the fact to the F_2 data to calculate the crossing-over value between *b* and *vg* in the female, and estimated it to be 17·8 per cent. The value is close to the standard value of 17·0 per cent (18·5 per cent, according to the recent census). For his 50 per cent crossing-over in the male, he writes: "Some other explanation (for example, of chromosomal mutation) must be offered".

In my opinion, Dr. Eloff used by mistake the other mutant, ebony for example, that appears in another chromosome. If so, the black body colour should be inherited independently with vestigial, and it would be quite the natural thing that there should be a 50 per cent crossing-over in the male. According to my understanding, his F_2 data seem to be nothing but the result of an independent segregation, although deviation was considerable.

DAIGORO MORIWAKI.

Furitsu Koto-Gakko,
Biological Institute,
Meguro, Tokyo.
March 6.

---

[1] G. Eloff, NATURE, 137, 151 (1936).

SINCE the appearance of my letter in NATURE of January 25, Prof. Tammes of Groningen has written to me as follows: "Gottschewski (of Berlin-Dahlem) is of opinion that the 'black' which you used was probably not the normal black but the so-called 'black Kreidel Holland' which is the same as sooty . . ."

The stock which I received from Groningen was only labelled 'black'. But it probably was a 'sooty' culture from stocks used by Dr. van Herwerden (and her student Kreidel), who got their cultures from America and Berlin-Dahlem. For some reason which is not clear to me at present, this 'sooty' stock was either labelled "black Kreidel Holland" or "black".

In order to make sure that it was the 'black' culture which was responsible for the independent segregation obtained, I this time made use of a vestigial stock from Berlin-Dahlem. The class representations of two series of repulsion back-crosses, the F_2 of which I have just finished counting, were as follows:

F_1 ♂ back-crosses: 204 BV, 235 bV, 194 Bv, 171 bv

$$\frac{BV + bv}{BV + bV + Bv + bv} = \text{approx. } 46 \cdot 6 \text{ per cent.}$$

F_1 ♀ back-crosses: 701 BV, 839 bV, 670 Bv, 698 bv

$$\frac{BV + bv}{BV + bV + Bv + bv} = \text{approx. } 48 \cdot 1 \text{ per cent.}$$

As the data refer to repulsion crosses only, the unequal representation of the classes may be explained by (1) difficult separation of bV and BV phenotypes in some experiments, with the result that BV phenotypes may be included in class bv; (2) poorer viability of classes homozygous for vestigial, namely, Bv and bv. Making allowance for these disturbing factors, it is quite possible that the correct percentage will be 50.

I am satisfied, therefore, that the stock I have used and which was labelled "black" may have been "sooty", so that the results must of necessity show independent segregation.

I regret the misleading results arrived at due to erroneous labelling of the stock, and I wish to thank Mr. Moriwaki for his comment.

Suggested Cases for Suspension of Rules of Nomenclature

ATTENTION of the zoological profession is invited to the fact that request for the "Suspension of the Rules" has been made in the following cases, on the ground that "the strict application of the Règles will clearly result in greater confusion than uniformity".

According to procedure, one year's notice is hereby published "making it possible for zoologists, particularly specialists in the group in question, to present arguments for or against the suspension under consideration".

Note A.—Suspend rules. Note B.—Insert in Official List with the type as given in parentheses.

Coelenterata.—*Monograptus* Geinitz, 1852 (*priodon*); A, B. *Retiolites* Barrande, 1850 (*geinitzianus*); A, B. *Graptolithus* Linn., 1768, to be suppressed; A.

Echinodermata.—*Luidia* Forbes, 1839 (*fragilissima*); A, B.

Nematoda.—*Anguina* Scopoli, 1777 (*Vibrio tritici*), to be suppressed; A.

Crustacea.—*Squilla* Fabricius, 1787 (*mantis*); A, B.

Insecta.—The so-called "Erlangen List" of 1801 to be suppressed.

Orthoptera.—*Locusta* Linn., 1758 (*Gryllus Locusta migratorius* Linn., 1758); *Phaneroptera* Serville, 1831 (*Gryllus falcatus* Poda, 1761); A. B.

Hymenoptera.—*Cimbex* Olivier, 1790 (*Tenthredo lutea* Linn., 1758); A, B. *Crabro* Fabricius, 1775 (*Sphex cribraria* Linn., 1767); A, B. *Lasius* Fabricius, 1805 (*Formica nigra* Linn., 1758); A, B. *Anthophora* Latreille, 1803 (*Apis pilipes* Fabr., 1775); A, B. *Ichneumon* Linn., 1758 (*Ichneumon extensorius* Linn., 1758); A, B. *Pimpla* Fabr., 1804 (*Ichneumon instigator* Fabr., 1793); A, B. *Ephialtes* Gravenhorst, 1829 (*Ichneumon manifestator* Linn., 1758); A, B. *Bracon* Fabr., 1805 (*Bracon minutator* Fabr., 1798); A, B. *Pompilus* Fabr., 1798 (*Pompilus pulcher* Fabr., 1798); A, B. *Bethylus* Latreille, 1802 (*Omalus fuscicornis* Jurine, 1807); A, B. *Prosopis* Jurine, 1807 (*Sphex signator* Panzer, [1798]); A, B. *Ceraphron* Jurine, 1807 (*Ceraphron sulcatus* Jurine, 1807); A, B. *Torymus* Dalman, 1820 (*Ichneumon bedeguaris* Linn., 1758); A, B. *Proctotrupes* Latreille, 1796 (*Proctotrupes brevipennis* Latreille, 1802); A, B. *Sphex* Linn., 1758 (*Sphex flavipennis* Fabr., 1793); A, B. *Ammophila* Kirby, 1798 (*Sphex sabulosa* Linn., 1758); A, B.

Lepidoptera.—In interpreting the generic names assigned by Freyer in his "Neuere Beiträge zur Schmetterlingskunde" to the species there described, each species is to be regarded as having been described by Freyer as belonging to the genus cited by him at the head of each description and not to the genus with which he actually associated the specific name. For example, Freyer described, under the genus *Hipparchia* Fabricius, a species to which he gave the specific name *eriphyle*, and which he proceeded to name *Papilio eriphyle* Freyer. Freyer is to be deemed to have described this species under the name *Hipparchia eriphyle*, and not under the name *Papilio eriphyle*. A.

Potamis Hübner, *Rusticus* Hübner, and *Mancipium* Hübner to be suppressed in favour of *Morpho* Fabr., *Helicopis* Fabr., and *Pontia* Fabr.; A.

Lepidoptera (Rhopalocera).—*Euploea* Fabr., 1807 (*Papilio corus* Fabr., 1793); A, B. *Satyrus* Latreille, 1810 (*Papilio actaea* Esper, [1780]); A, B. *Argynnis* Fabr., 1807 (*Papilio paphia* Linn., 1758); A, B. *Vanessa* Fabr., 1807 (*Papilio atalanta* Linn., 1758); A, B. *Euthalia* Hübner, [1823] (*Papilio lubentina* Cramer, 1777); A, B. *Nymphidium* Fabr., 1807 (*Papilio caricae* Linn., 1758); A, B. *Colias* Fabr., 1807 (*Papilio hyale* Linn., 1758); A, B.

Species in parentheses are to be declared the types *Lycaeides* Hübner, [1823] (*Papilio argyrognomon* Bergstrasser, 1779); A. *Agriades* Hübner, [1823] (*Papilio glandon* Prunner, 1798); A. *Polyommatus* Latreille, 1804 (*Papilio icarus* Rottemburg, 1775); A. *Euchloë* Hübner, [1823] (*Euchloë ausonia* Hübner, var. *erperi* Kirby, 1871). *Princeps* Hübner, [1807] and *Orpheides* Hübner, [1823] (*Papilio demodocus* Esper, 1798). *Carcharodus* Hübner, [1823] and *Spilothyrus* Duponchel, 1835 (*Papilio fritillarius* Poda, 1761); A.

Effect of Oxygen on the Auroral Afterglow

During the past year, I have been studying the effect of oxygen on the auroral afterglow in nitrogen. This afterglow is the one the spectrum of which corresponds to the nitrogen part of the auroral spectrum. Attention has been directed elsewhere[1] to some of the more general results of these experiments, but in view of the recent communication by Vegard and Tønsberg[2] on the difference between the spectra of sunlit and ordinary auroras, one aspect of my experiments seems worth special mention here.

Oxygen is introduced into the tube until the blue-green afterglow with continuous spectrum appears. As the tube is allowed to run, the oxygen slowly disappears and the spectrum of the afterglow undergoes some striking changes. The stage of the afterglow which follows the initial blue-green continuous stage is one in which the glow consists of a blue-green background that fills the entire bulb, possesses a banded spectrum and lasts about ten seconds. Superposed on this blue-green glow is an orange-red flash of shorter duration and greater intensity than the background glow. This flash is confined to the centre of the bulb, and its spectrum consists of first positive bands of N_2 and some relatively weak first-negative bands.

Visual examination as well as photographic reproduction of the spectrum shows that the effect of the oxygen is to enhance the first-positive bands relative to the first-negative group. This phenomenon agrees very well with the results of Vegard and Tønsberg on sunlit auroras. The blue-green continuous glow is generally regarded as resulting from the reaction between ozone and nitric oxide. There is therefore probably some ozone present in the orange-red flash stage that follows when the oxygen concentration is slightly reduced.

It is of interest to note that the green auroral line is weaker in this stage of the glow than one would expect, and this also is in agreement with Vegard and Tønsberg's results. It is believed that further study of this orange-red flash will reveal detailed agreement between the laboratory phenomenon here described and the sunlit auroras.

Ground State Vibrational Frequencies

A STUDY of the ground state vibrational frequencies of diatomic molecules in relation to the Periodic Table has shown that the arithmetic mean ω_m of the vibrational frequencies of the two elementary molecules A_2 and B_2 which belong to the same Periodic Group is approximately equal to the frequency of the compound molecule *AB*. All the relevant data are collected in the accompanying table.

Group 1			Group 5			Group 6			Group 7		
Mol.	ω	ω_m	Mol.	ω	ω_m	Mol.	ω	ω_m	Mol.	ω	ω_m
Li_2	352		N_2	2360		O_2	1568		Cl_2	565	
Na_2	159		P_2	778		S_2	727		Br_2	324	
K_2	93		As_2	432		Se_2	388		I_2	214	
Rb_2	58		Sb_2	268		SO	1124	1148	ICl	385	389
Cs_2	41		Bi_2	173		SeO[5]	(910)	978	IBr	267	269
LiK	(207)	223	PN[2]	1337	1569				BrCl	(440)	445
LiRb	(185)	205	AsN[3]	1063	1396						
LiCs	(170)	196	BiSb[4]	220	221						
NaK	123	126									
NaRb[1]	107	109									
NaCs	96	90									

Bracketed values are uncertain.

In Group 5 the BiSb molecule conforms to this rule, whereas the PN and AsN molecules do not. The ω value of the former molecule definitely refers to the ground state, as it is derived from absorption measurements, but there is no such certainty in the case of the latter molecules as their ω values are derived from emission spectra. It is suggested, therefore, that these discrepancies are due to the fact that the ω values presented here for PN and AsN do not refer to their ground states but to excited states. If this is so, it is probable that the actual ground state frequencies will be of the order of 1570 cm.$^{-1}$ and 1400 cm.$^{-1}$ respectively.

This subject will be discussed in greater detail in a future publication.

A Second Sheath near the Cathode of an Arc Discharge

IN the course of some investigations on arc discharges with oxide-coated cathodes in rare gases, a new dark sheath with a sharp boundary was seen between the well-known Langmuir double space-charge sheath on the cathode and the light of the arc plasma. Fig. 1 shows diagrammatically (*a*) the cylindrical (indirectly heated) barium – strontium oxide coated cathode (viewed end-on), with (*b*) the well-known absolutely dark space-charge sheath, a few tenths of a millimetre in width and concentric with it, and (*c*) the almost dark sheath a few millimetres wide, followed by (*d*) the light of the plasma.

The thickness of this new sheath (*c*) varies approximately inversely with the square root of the current density and only slightly with the gas pressure. At low current density, for example, 0·1 amp. per cm.^{2}, the sheath becomes very indistinct. This dark sheath is only visible in a definite pressure range :

In helium	between	3	and	0·7	mm.	rather indistinct
„ neon + (0·1–1 per cent argon)	„	0·6	„	0·2	„	sharp
„ argon	„	0·2	„	0·02	„	„
„ krypton	„	0·14	„	0·01	„	„
„ xenon	„	0·08	„	0·008	„	„
„ mercury vapour	„	0·03 (60° C.)	and	0·007 (40° C.)		sharp.

In pure neon the sheath was barely visible. In argon, krypton and xenon the colour changes at the lower pressure limit mentioned above and at lower pressures a sheath is observed, which is brighter than the arc plasma, with almost the same dimensions as the dark sheath. At still lower pressures it disappears. In hydrogen, at 0·5 mm., a bright sheath is observed round the cathode with about the same thickness as in the case of the noble gases. Below 0·1 mm. we can see in hydrogen concentric with the dark space-charge sheath a bright and an almost dark sheath followed by the light of the discharge plasma (very distinct at 0·005 mm).

These last phenomena were also observed in argon (though very indistinct) at such a low pressure that the bright sheath had disappeared.

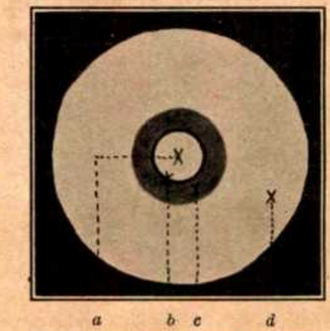

FIG. 1. Diagram of glow from an oxide-coated cathode, in argon at 0·05 mm. pressure, current 2·0 amp., diameter of cathode 4 mm., emitting surface 2·9 sq. cm.

A more extensive report will be published in the Dutch journal *Physica*.

Parallel-Plane Diode Magnetron

IN the discussion on a paper[1] by W. E. Benham on "Electronic Theory and the Magnetron Oscillator", it is remarked that although oscillations should be expected from plane diodes with magnetic field[2], no experimental evidence had been brought forward to support this.

We have constructed a plane diode of the Müller[3] type consisting of a plane indirectly heated oxide-coated cathode, 17 mm. in diameter, and an anode the two plane plates of which were approximately 15 mm. in diameter, situated on either side and at 1 mm. distance from the cathode. The anode plates provide the capacitance of the oscillating circuit, and the conductor joining these two plates (assumed for calculation in this case to be a ring of 21 mm. in diameter), provides the inductance. The anode current is fed to this ring at a voltage node. The arrangement can be seen from Fig. 1.

It was hoped with this valve to obtain diode oscillations[3] of the order of 30 cm. without a magnetic field, but having failed to detect any, owing perhaps to the lack of exact symmetry in the apparatus, a magnetic field was applied parallel to the electrodes. Weak oscillations could be detected with a Lecher wire system coupled capacitatively to the valve, together with rectifier and sensitive galvanometer.

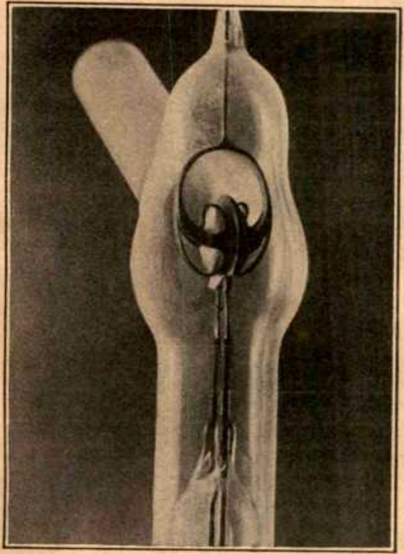

FIG. 1. Parallel-plane diode magnetron.

Until a further valve is built, little more can be said than :

(1) the oscillations occur where the magnetic field starts to cause a reduction in the anode current,

(2) the oscillation intensity falls off as the direction of the magnetic field is altered from that parallel to the electrodes, to that perpendicular to the plane of the electrodes,

(3) the wave-length of the oscillations is of the order of that determined by the oscillating circuit (the anode plates plus connecting wire).

Collisional Friction Frequency in the Ionosphere at Allahabad

APPLETON[1] has shown that for the ordinary ray the integrated absorption coefficient k for absorption in the deviating region (that is, in the region where μ approaches zero) may be calculated from the following formula :

$$-2\int_{\mu=1}^{\mu=0} k\,dh = \ln \rho_0 = -\frac{\nu}{2c}\left(P_0'-P_0\right), \quad . \; . \; . \quad (1)$$

where ν, the collisional friction frequency per electron per second, is assumed to be constant throughout the deviating region ; ρ_0 is the reflection coefficient for the ordinary ray ; P'_0 is the group path ; and P_0 is the optical path of the wave.

Late in the night after the magneto-ionic splitting has taken place and the ordinary ray has undergone much group retardation, we are justified in assuming that

$$\triangle\,(\ln \rho_0) = -\frac{\nu}{2c}\,\triangle\,(P_0') \quad . \; . \; . \quad (2)$$

Thus if we plot $\ln \rho_0$ against the equivalent height $P_0'/2$, we should expect a straight line, the slope of which will give us the value of ν. The observations made in this laboratory during last winter show the validity of formula (2) and give an average value of ν of $1 \cdot 2 \times 10^4$ per electron per second.

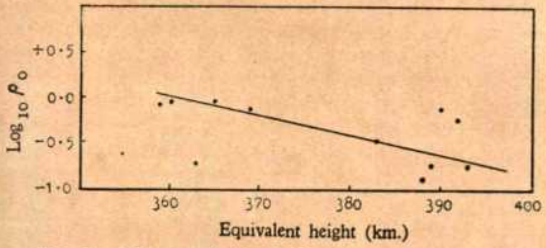

FIG. 1. *F*-layer reflections, March 1, 1936, time 0319–0402 I.S.T.

In Fig. 1, $\log_{10} \rho_0$ has been plotted against the equivalent height for reflections from the *F*-layer. ν comes out to be $1 \cdot 2 \times 10^4$ per electron per second.

The value of ν has also been determined by similar methods in England by Eckersley[2] and Farmer and Ratcliffe[3]. Eckersley has found $\nu = 3 \cdot 6 \times 10^3$ in the daytime for the *F*-region, while Farmer and Ratcliffe's night-time value of ν for the *F*-region is $2 \cdot 1 \times 10^3$ and the daytime value is $1 \cdot 2 \times 10^3$ per electron per second. Thus we see that the value found by us differs considerably from that found by workers in England. At present it is not possible to account for this difference, unless more data extending over a large period are available.

Further observations are being made and details will be published elsewhere.

Sensitivity of Photographic Plates in the Region λλ 2500–2100 A.

IT is well known that the sensitivity of an ordinary photographic emulsion begins to fall rapidly just below λ 2500 A., and is very low at λ 2100 A. This fall is due to the absorption of short-wave radiation by the gelatin of the emulsion. It is commonly stated[1] that higher sensitivity in this region may be obtained by greatly reducing the gelatin content of the emulsion, as in the Schumann plate, or by bathing an ordinary plate in a fluorescent substance which can convert the short waves into radiation able to penetrate the gelatin.

Having had occasion recently to photograph spectra of low intensity in this region, we were surprised to find that better results could be obtained with ordinary plates than with plates recommended as having much higher ultra-violet sensitivity. We have therefore carried out some experiments with the view of clearing up this apparently anomalous behaviour.

The procedure was as follows. A heavy-current discharge tube, through which passed a slow stream of air, provided a steady source of the γ-bands of nitric oxide. These bands are characterised by strong, well-defined heads, with long branches slowly degraded in the direction of shorter wave-lengths. The range of intensity thus available makes this band system very suitable for comparison of plate characteristics in the ultra-violet. Using a Hilger *E*2 quartz spectrograph, identical sets of exposures in logarithmic steps were made on each plate under test. Ordinary plates (Imperial) were compared in this way with Schumann plates (Hilger and Agfa), special ultra-violet plates (Eastman and Agfa), *Q*-plates (Ilford), and Imperial plates treated with such common sensitisers as anthracene, sodium salicylate, vaseline and various mineral oils.

In most cases, especially when the source is weak, the spectroscopist wishes

(*a*) to obtain a measurable record of the spectrum with the least possible exposure, and

(*b*) to reproduce, as a range of perceptible density differences, the intensity differences present in the actual spectrum.

Our results show that

(*a*′) every plate tested, except the Ilford *Q*2 plate, gives less blackening for short exposures than does an ordinary plate. That is to say, an ordinary plate fulfils condition (*a*) better than the 'sensitised' plates, with this one exception.

(*b*′) the 'sensitised' plates are capable of showing more intensity contrast than ordinary plates, because they have a greater saturation density. This increased density, however, is obtained only by prolonging exposure beyond that which is needed to reach saturation with ordinary plates.

If, therefore, it is desired merely to detect a weak spectrum in this region, it is undesirable to use 'sensitised' plates. If, on the other hand, the source of radiation is intense, or short exposure time is not aimed at, these plates will give greater contrast and higher saturation density than ordinary ones.

It is perhaps also worth noting that considerable over-exposure in this region does not produce on an ordinary plate densities comparable with those attainable in the nearer ultra-violet or visible region. Apart altogether from considerations of fogging, excessive exposure is detrimental in that it smooths out what little intensity contrast is present in a correctly exposed plate. This is shown by the fact that, on an over-exposed plate, even such a spectrum as that of NO appears almost continuous.

A full account of the experiments will be published shortly.

Nova Lacertæ, 1936

SLIT spectra of the nova have been obtained at this Observatory on every night, with one exception, since the discovery was announced on June 19.

The most prominent feature in the spectra is the broad emission bands of the Balmer series of hydrogen, $H\alpha$ being particularly bright. The width of the $H\beta$ and $H\gamma$ emissions on the evening of June 22 was about 50 angstroms. These emissions are flanked on the side of shorter wave-length by rather weak absorption lines. The more displaced component of the two $H\gamma$ absorptions indicated a velocity of about -1100 km./sec. on the morning of June 20; this rose to about -1900 km./sec. by the evening of June 22.

Fe II, Ti II, Mg II, and Ca II are also represented by broad weak emission bands and displaced absorption lines. These absorption lines are weak and hazy, but the sharp interstellar *H* and *K* lines are strongly shown on a plate taken on the evening of June 22.

The general appearance of the spectrum is in sharp contrast with that of Nova Herculis, 1934, at a corresponding stage of development.

The Background of the Galaxies

IN NATURE of May 30, M. Leontovski[1] shows that "To a most sensitive eye, the background of the galaxies would appear as a dark red." Since the irresolvable background consists of nebulæ receding with nearly the speed of light, the age of these nebulæ, as observed, reckoned in our own time-scale, must be approximately one half the present age of our own surroundings; that is, if *t* is the conventional value of the age of the universe, $\frac{1}{2}t$ is the age of the observed background[2]. Combining these results, we see that the background realizes the poet's dream of

"A rose-red city, half as old as time."[3]

Glycosides of Madder

THE glycoside obtained from various species of *Galium* and *Rubia* already described in NATURE[1] has now been found to be a primveroside of purpurin carboxylic acid.

The sugar of ruberythric acid, the glycoside of alizarin, which has been known for many years, has been isolated in the pure crystalline condition from the products of enzymic hydrolysis and identified as primverose. A primveroside of rubiadin has also been obtained from the roots of *Galium Verum*.

The three glycosides are rapidly hydrolysed by enzymes present in members of the Primulaceæ. They would appear to be the first examples known of primverosides occurring in the Rubiaceæ.

Points from Foregoing Letters

NEW experiments to find whether there is a correlation between the scattering of gamma radiation and electron recoil are described by Dr. J. C. Jacobsen. In agreement with Bothe and Maier-Leibnitz, and unlike Shankland, the author finds a number of coincidences which is well beyond the experimental error. Commenting on these results, Prof. N. Bohr considers that the grounds for serious doubts concerning the validity of conservation of energy and momentum in atomic phenomena are largely removed. The root of the still unsolved difficulties of quantum electrodynamics may be looked for, he states, in the atomistic nature of electricity, which is as foreign to the classical physical theories as the quantum of action itself.

With reference to the complex molecular nature of solid sulphur trioxide, Prof. H. E. Armstrong directs attention to its value as a sulphonating agent, and recalls incidents in connexion with its early preparation by Frankland.

To account for the similarity in the graphs representing the rate of thermal decomposition and the rate of oxidation of formaldehyde and of acetaldehyde, Prof. M. W. Travers suggests that short-lived intermediates are formed in both cases.

A new vitamin, 'P', which cures pathological permeability of the walls of capillaries to plasma protein, is reported by St. Rusznyák and Prof. A. Szent-Gyorgyi. The new vitamin, closely allied to vitamin C, is found in Hungarian red pepper and lemon juice, and is apparently flavon or flavonol glycoside, one of the vegetable dyes.

Adenylic acid and adenosine (obtained from muscle or yeast) are found by Dr. T. W. Birch and Dr. L. W. Mapson to accentuate considerably the slowing down of the heart-beat (bradycardia) produced in rats by deficiency of vitamin B_1. The authors find, further, that vitamin B_1 helps in the elimination of adenylic acid and suggest that, when the vitamin is absent, there is an accumulation of adenylic acid and that it and similar decomposition products of nuclein are the cause of the bradycardia, not lactic acid, as sometimes stated.

The concept of a pair of equivalent particle-observers, as employed by Milne and Page, is criticised by Prof. J. L. Synge, who deduces that any two particle-observers are equivalent, and their relative velocity is zero for suitably chosen equivalent clocks.

The variations of the magnetic induction with the field applied are found by K. Mendelssohn and R. B. Pontius to follow a smooth and nearly reversible curve in the case of a sphere of tin at very low temperature (in the supra-conducting state), while in a cylindrical specimen, the graph shows step-wise changes, with considerable hysteresis. This behaviour agrees with the assumption that the time effects observed indicate a slow expansion or contraction of macroscopic supra-conducting regions.

Examples showing how the exact value of physical constants (such as density and boiling point) of pure liquids can be estimated with a high degree of accuracy from the change in boiling point of the liquids as they become purer on distillation are given by Dr. M. Wojciechowski and Dr. E. R. Smith.

A greatly increased consumption of oxygen by cartilage tissue, upon addition of methylene blue, is reported by E. G. L. Bywaters. Under ordinary conditions, cartilage splits glucose into lactic acid without the use of oxygen.

Dr. S. Dobinski finds that the haloes obtained by diffraction of electrons on a copper surface polished in air are due to cuprous oxide. Polishing in absence of air gives rise to different haloes of such size as might be expected from degeneration of the usual copper pattern.

On placing living tissue cells in pure water or in a medium free from salts, Prof. H. Grossfeld finds that the cells take a globular shape, and that a vivid Brownian movement and increase in the number of granules takes place. The author ascribes these reversible changes to the loss of diffusible electrolytes, which produces a slow coagulation of the cytoplasm.

A group of symptoms observed when rats have suffered severe injuries from various agents (cold, surgical injuries, poisoning), which seems independent of the nature of the damaging agent, is described by Prof. H. Selye, who describes it as a "general adaptation syndrome". This syndrome, which develops in several stages, includes decrease in the size of thymus, spleen, lymph glands and liver, disappearance of fat tissue, formation of acute erosions in the digestive tract, increase in adrenals, etc.

Prof. J. Kaplan finds that when oxygen is introduced into the auroral afterglow in nitrogen, the spectrum of the resulting afterglow resembles very closely the spectrum of sunlit auroras as reported by Vegard and Tønsberg. He believes that the effect is brought about by ozone as postulated by Vegard and Tønsberg.

Evidence is submitted by Dr. Howell that the ground state vibrational frequency of a molecule AB is very nearly equal to the mean of the frequencies of the elementary molecules A_2 and B_2, where A and B belong to the same group of the Periodic Table.

A new 'dark sheath', with a sharp boundary, near the cathode of an arc discharge between the Langmuir double space-charge sheath on the cathode and the light of the 'arc plasma', is described by N. Warmoltz.

According to theoretical considerations put forward by J. Muller, electromagnetic oscillations are to be expected from a parallel-plane diode magnetron, when the magnetic field is arranged parallel to the plane of the electrodes. D. M. Tombs observes oscillations of the order of 30 cm. confirming this.

A. Hunter and Dr. R. W. B. Pearse find that in the region λλ 2500–2100 A., certain specially sensitised ultra-violet plates are actually less sensitive than ordinary plates when exposures are short or the radiation is weak. 'Sensitisation' in general increases contrast and maximum attainable density, but decreases threshold speed.

Spectra of the new star reported in last week's NATURE are briefly described by Drs. T. W. Wormell and J. C. Dobbie. The hydrogen absorptions indicate velocities which have risen from 1100 to 1900 km./sec. in two and a half days. Certain enhanced metallic lines are also present, in displaced positions, and the sharp lines of interstellar calcium are a prominent feature.

Research Items

Fertility and Contraception in the United States

DATA relating to the reproduction histories of 30,949 women (white and negro) overtly fertile in 1931 and 1932, and residing in or near twenty-six large cities in fifteen States east of the Mississippi and north of the southernmost tier of States, have been collected and are in course of analysis by Prof. Raymond Pearl. An important factor in any discussion of this material is the extent and effectiveness of contraception. It can alter completely the expression of variation in natural innate fertility. An attempt to evaluate the influence of this factor (*Science*, 83, May 22, 1936) shows that among the white population under investigation, 54 per cent have not practised contraception and among the negroes 83 per cent. Contrasting the two classes of contraceptors and non-contraceptors in white and negro respectively, it appears that in white and negro non-contraceptors, the pregnancy rates are identical; but among contraceptors, in the whites contraception is effective in reducing pregnancy 25–50 per cent in the various age classes, while among negroes it is without significant statistical effect in lowering the pregnancy rates below those of comparable classes of non-contraceptors. This confirms the experience of clinics that negroes do not practise contraception effectively, even after instruction. Clearly if no other variables were involved, this would result in a change in the relative proportions of the two elements in the population, which would be apparent in a very short time. There is, however, a much higher rate of production wastage (abortions, miscarriages and still-births), largely owing to the prevalence of venereal disease, among the negroes. This acts as one of several compensating factors in the birth-rate.

Antiscorbutic Activity of a Derivative of Gluconic Acid

IT is now known that a number of compounds chemically related to *l*-ascorbic acid or vitamin C can exert some degree of antiscorbutic activity. An addition to the list is announced in a letter addressed to the Editor by Prof. B. A. Lawrow, Prof. W. M. Rodionow, E. M. Bomdas and N. S. Jarussowa, of the Vitamin Department of the Institute of Nutrition, Moscow. They have found that the methyl ester of 2-ketogluconic acid exerts antiscorbutic activity in guinea-pigs in doses of 100 mgm. or more: 50 mgm. had a curative action in about half of a group of animals suffering from scurvy, but 25 mgm. had very little effect. This ester is an intermediate product in the synthesis of *d*-arabo-ascorbic acid, which has about one-twentieth of the antiscorbutic potency of vitamin C itself (see S. S. Zilva, *Biochem. J.*, 29, 1612; 1935). It thus appears that the ester of ketogluconic acid has about 1 per cent of the activity of *l*-ascorbic acid or vitamin C. The chemical difference between the two ascorbic acids lies in the position of a hydroxyl group in the chain. The Russian authors do not discount the possibility that the gluconic ester is converted first into *d*-arabo-ascorbic acid in the animal body and that the antiscorbutic activity is due to this compound: they also state they they are extending their investigation to include an examination of the action of the ester of ketogulonic acid, which occupies a corresponding position in the synthesis of *l*-ascorbic acid. The question whether antiscorbutic activity depends upon the presence of a cyclic structure in the molecule or can also be exerted by open-chain compounds must await further investigation, but may be difficult to decide if the conditions of conversion *in vitro* can be duplicated in the body.

Sex Change in a Fish

THE actual change of sex that takes place in a teleostean fish, *Sparus longispinis*, is the subject of a memoir by Kinoshita (*J. Sci. Hiroshima Univ.*, Ser. B, Div. 1, 4; 1936). In early life the gonad consists of a thread-like testis. Shortly after, oocytes make their appearance in tissue alongside the testis which now contains ripe spermatozoa. More of them make their appearance until a hermaphrodite condition is realized, but only functional sperms are produced. The final stage is brought about by the degeneration of the gonad of one sex, either male or female, thus leaving the old fish of the other sex. It is only when this stage is reached that functional ova are produced.

Fungi and Graft Unions

THE partnership between stock and scion of a grafted plant is usually well adjusted. There is, however, undoubted evidence that fruit-tree stocks can influence the type of scion growth, and the scion can, under different conditions, control growth of the whole tree. Mr. T. E. T. Bond has investigated the possibility that such relations would have an effect upon the relative susceptibility of herbaceous stocks and scions to attack by disease-producing fungi (*Ann. App. Biol.*, 23, No. 1, 11–29, February 1936). Various graft combinations of potato, tomato, woody nightshade, deadly nightshade, thorn-apple, *Physalis* sp. and henbane were prepared, and were inoculated on one side of the union with either of the fungi *Phytophthora infestans* or *Cladosporium fulvum*. The resulting attacks by these fungi were the same as upon ungrafted material, thus showing no influence of the other participant in the graft union, either in preventing, or helping, fungal attack in the herbaceous plants used for the experiment.

A Disease of the Japanese Laurel

THE common variegated Japanese laurel, *Aucuba japonica*, is but rarely the host of any fungus or bacterial parasite. Dr. G. Trapp has, however, isolated an organism, *Pseudomonas aucubicola*, a new species, which is very closely concerned in a 'die-back' disease of this popular shrub ("A Bacillus isolated from Diseased Plants of *Aucuba japonica* (Thunb.)", *Phytopath.*, 26, No. 3, 257–265, March 1936). Though the organism was consistently isolated from stem, leaf and root lesions of infected plants, very intensive attempts to re-inoculate healthy plants failed to reproduce the malady. It is considered that *P. aucubicola* is not a primary parasite, but can avail itself of a slightly diseased condition induced by some other cause. Morphological, cultural and physiological characters of the organism are set forth at length in the paper.

Atmospheric Vorticity

THE *Journal of the Faculty of Science*, Imperial University of Tokyo, Section 1, vol. 3, part 2, August 1935, contains a number of meteorological papers dealing with atmospheric vorticity. The first, by K. Nakata, with an introduction by Prof. S. Fujiwhara, is a study of the vertical component of vorticity. A number of synoptic weather charts are shown on which are drawn lines of isovorticity together with ordinary isobars for sea-level, for the neighbourhood of Japan for certain dates in the winters of 1922 and 1923. These show that the areas of positive (cyclonic) and negative (anticyclonic) vorticity generally nearly coincide with the cyclonic and anticyclonic areas, but that the two pairs of systems often differ in detail; that the different systems travel together; but that the distribution of vorticity is irregular in the regions lying between an anticyclone and a cyclone. The centres of maximum and minimum vorticity, in spite of the irregularities just mentioned, appeared to coincide very nearly with the main centres of low and high pressure. Later papers in the series by other Japanese writers extend the relationship to features other than the distribution of atmospheric pressure, including cloud and rainfall, and deal with the case of the typhoon. Very little is said of the difficulties that must have arisen from lack of sufficient observational material, and in the application of the classical hydro-dynamical equations to a complex and highly compressible fluid like the atmosphere; it is difficult to assess the importance for meteorology of the very laborious and difficult computations involved in this attack upon a subject which is undoubtedly of the greatest importance for progress in meteorology.

Electrical Contacts

ALL engineers who are familiar with the working of spark coils and the phenomena which take place where the brushes press on the commutator of a dynamo realize the importance of the study of electrical arcs and discharges, but it is only recently that their effects on the resistances of the materials in contact have been considered. In *World Power* of May, G. Windred has given a useful review of recent literature on the subject. The value of the contact resistance between two metals depends largely upon the conditions at the interface between them, but it is also largely affected by the formation of oxides on the faces. It is known that copper oxides produce a marked increase on the contact resistance. For a given current this increases the heating and the cumulative rate of deposit of the oxide. At a certain critical temperature, there is a sudden fall in the contact resistance, and this is of importance in the design of heavy-current contact breakers. The main factors which influence the life of electrical contacts are their hardness and their resistance to the effects of arcing. The relays used in modern telephone practice must operate faultlessly over long periods of time and with the minimum of inspection; their effective life depending on the duty cycle which they perform and the amount of attention which they receive. The disadvantages of using copper and brass are their low melting points and their susceptibility to corrosion. This led in the early days to the use of precious metals for electrical contacts. Papers by Carter and Kingsbury published in America (*Bell Journal Reprints*, April 1928) contain practically all our knowledge of this important subject. Kingsbury deals with the important subject of contact erosion and gives experimental data obtained from eight different contact metals showing their losses in weight, volume and atomic proportions relative to platinum.

Organic Derivatives of Silicon

IN the Bakerian Lecture to the Royal Society delivered on June 25, Prof. F. S. Kipping reviewed the work of the past thirty-five years at University College, Nottingham, on organic derivatives of silicon. With the object of determining whether silicon could give rise, like carbon, to dissymmetric molecules, a number of derivatives belonging to the two types $\mathrm{SiR_1R_2R_3R_4}$ and $\mathrm{(R_1R_2R_3Si)_2O}$ and each containing at least one aromatic nucleus, were prepared. These optically inactive compounds were converted to sulphonic acids, and resolutions with active bases were attempted. In each case only one active base gave the desired result. A remarkable feature was that in many cases the *d*- and *l*-acids, when combined separately with another active base, gave salts which were indistinguishable in all physical properties, including specific rotation. In the course of other investigations, it was found possible to direct attention to the great differences in behaviour between similarly constituted compounds of carbon and silicon. Thus the chlorides $\mathrm{SiR_3Cl}$ are easily hydrolysed by cold water to silicols $\mathrm{SiR_3OH}$, which pass readily into oxides $\mathrm{SiR_3.O.SiR_3}$. In no case has the formation of a simple silicone, $\mathrm{R_2Si{:}O}$, been observed, and indeed it seems probable that the group $\mathrm{>Si{:}O}$ does not exist, nor is there any evidence of the formation of an ethylenic bond between carbon and silicon or between two silicon atoms. The diols $\mathrm{SiR_2(OH)_2}$ and triols $\mathrm{SiR(OH)_3}$ give rise to complex mixtures by progressive condensations, the study of which throws light on the structure of mineral silicates. Acids of the type $\mathrm{R.SiO.OH}$ are probably not formed. The general conclusion is that corresponding carbon and silicon compounds show very little similarity in behaviour, only a few types of carbon compounds being represented by analogous derivatives of silicon.

Monogenic Functions

A FUNCTION of a complex variable is called monogenic at a point if at that point it possesses a unique finite derivative. It is well known that such a function satisfies the differential equations of Cauchy-Riemann; but the converse is not true. The problem of determining conditions that are sufficient for monogeneity and yet are free from unnecessary restrictions has not yet been completely solved, but an account of recent progress is given by Prof. D. Menchoff of Moscow ("Les conditions de monogénéité"; Actualités scientifiques et industrielles 329. Paris: Hermann et Cie., 1936). It is surprising to find that the demonstrations seem necessarily to involve complicated ideas of the modern theory of functions, even when the properties dealt with are apparently independent of these ideas. Perhaps some mathematician will take up the challenge, and supply the simpler proofs which, one is tempted to say, must exist.

The Indian Institute of Science, Bangalore

IN 1926 the Government of India appointed a committee with Sir William Pope as chairman to report upon the Indian Institute of Science, and one of its recommendations was that the activities of the Institute should be subject to review by a committee every five years. Early this year, Sir James Irvine was appointed chairman of the statutory quinquennial committee, and the issue of the report of this committee is awaited with interest. It is untimely, therefore, that the March issue of our Calcutta contemporary, *Science and Culture*, should publish a severely critical article on the present administration of the Institute. Anyone cognisant of the large volume of original work which has issued from the Institute since its foundation cannot doubt that it has more than justified the hopes of its munificent founder, the late Mr. J. N. Tata. The two main heads of the recent criticisms would appear to be (*a*) that the work of the Institute is too academic and (*b*) that, since the students are drawn very largely from South India, it is no longer an all-India research institute.

Whilst it may be true that much of the work carried out in the laboratories of the Institute is concerned mainly with problems of purely scientific interest, it is difficult to see how this could be otherwise. The research work in the Institute is done by young students who go there for a training in the methods of research. If they are not to be discouraged in their early years, it is essential that they should be assigned problems likely to yield results within a reasonable time. Furthermore, we very much doubt if it is possible to undertake *ad hoc* research on industrial problems. The industrial research institutions in Great Britain work in close contact with established industries, and they study fundamental problems related to these. It is very rare indeed that a new industry results directly from an isolated piece of research. We are of opinion that the Indian Institute of Science can best assist industrial development by working in collaboration with industry, as do the universities in Great Britain with Imperial Chemical Industries, Ltd.

The contributions of the Institute to industrial development have not been negligible; we need only instance the valuable researches made in collaboration with the Forest Research Institute at Dehra Dun on the causation of sandal wood disease, the investigations on wireless transmission in the tropics, and the work leading to the establishment of the sandalwood oil and white lead industries.

All industrial advancement is dependent upon pure scientific research, and it is a matter for congratulation that Sir C. V. Raman, the present director, has already built up a school of research in physics and that he was able to attract as a visitor to Bangalore so eminent a theoretical physicist as Dr. Max Born. Whilst the rapid development of research in Indian universities, not foreseen by its founders, has doubtless made necessary a new orientation of the activities of the Institute, we cannot doubt that it will continue to play a great part in the scientific advancement of India.

Progress in Atomic Physics

CONFERENCE AT COPENHAGEN

PROF. NIELS BOHR held a conference on atomic physics on June 17–20 in the Institute for Theoretical Physics at Copenhagen. About eighty physicists attended the discussions, including many from foreign countries.

The outstanding communication to the conference was a paper by W. Heisenberg on the quantum-mechanical theory of cosmic ray showers. Up to the present, no explanation of the fact that particles of very high energy can produce simultaneously, or in a single process, a large number of secondary particles, has been given in terms of the quantum theory of electrodynamics. Such showers of secondary particles have been observed by Hoffmann, Blackett and other experimenters.

According to quantum electrodynamics, the effective cross-sections for the simultaneous formation of n pairs of electrons lead to an extremely small probability for the occurrence of large showers. This calculation was made on the assumption that only the ordinary known electrical forces are of importance in the interaction between charged particles.

The phenomenon of β-disintegration has, however, suggested the idea, as in Fermi's theory, that there exist interaction forces of a new type between electrons and heavy elementary particles such as protons and neutrons. In this new type of interaction, a fourth elementary particle, the neutrino, probably takes part, as has been suggested by Pauli. Without the neutrino, it is impossible to preserve the law of the conservation of energy in the description of β-disintegration. It follows from the existence of these new interaction forces that an electron and neutrino can be created in an atomic nucleus, the electron being emitted as a β-ray, as Fermi pointed out.

Heisenberg has given a general proof that all interaction forces of the type that produce β-disintegration lead to the production of multiple processes and particles, when initiated by particles of high energy. The process may be of the following sort. A high-speed proton strikes a nucleus and produces in the field of the nucleus a great number of β-rays in one elementary action. Heisenberg suggests that the mechanism of the cosmic ray showers is of this type.

He has succeeded in calculating the minimum energy needed by the incident particle to produce this effect, and finds that the order of magnitude is in quite good agreement with the experimental observations of cosmic ray energies.

It is hoped that this new conception of the interaction between elementary particles will suggest methods of solving the difficulties in the theory of quantum electrodynamics, which arise from the incomplete knowledge of the physical laws governing the behaviour of particles of high energy.

V. Weisskopf discussed the Dirac theory of positrons, and showed that its formulation can be simplified, and some of its paradoxes removed. P. Jordan discussed the theoretical possibility of conceiving a light quantum as a pair of neutrinos. M. Born gave an account of his theory of quantum electrodynamics. Kalckar and Bohr gave a detailed mathematical account of their theory of nuclear disintegration. O. R. Frisch and G. Placzek gave an account of the structures of energy levels in heavy nuclei, and the possibility of investigating it by means of the absorption of slow neutrons. Rosenfeld and Bohr discussed the problem of the measurement of charges, and the importance of field and charge fluctuations for the definition of theoretical concepts.

The course of the discussions was, as always, directed by the masterly fundamental criticisms of Bohr. On these occasions, when so many able theorists are gathered together, it is clear that Bohr's physical insight is the power which contributes most to the advance of theoretical atomic physics, and creates the conditions which fertilize the mathematical abilities of theoretical workers elsewhere.

The most interesting and important paper on experimental physics was, perhaps, Jacobsen's account of his repetition of the Shankland experiment (see p. 24 of this issue). Shankland failed to observe coincidences between recoil electrons and scattered quanta when observing with counters at the angles expected according to the Compton theory of the photon scattering process. He used γ-rays from radium, which cover a large range of frequencies. Jacobsen, and Bothe and Maier-Leibnitz have now repeated the experiment with the almost non-chromatic γ-rays from thorium C′. They have taken great care in defining the angles used, and have found the expected number of coincidences. These results are confirmed by some less well-defined experiments by Fermi's collaborators. Thus the suggested failure of the conservation of energy in the Compton effect, so eagerly seized upon by Dirac, in order to get rid of some of the difficulties found in the formulation of a satisfactory relativistic quantum dynamics, is not confirmed. Bohr, Pauli, Heisenberg and other theoretical workers expressed satisfaction at this result, and hoped that further discoveries would mitigate the difficulties on which Dirac comments (see p. 24).

Heitler reported that Anderson has withdrawn his claim that the energy lost by fast electrons in the cosmic rays is much less than expected on general theoretical grounds.

Miss Meitner gave an account of some work on the radioactive effects produced in uranium by the action of slow neutrons. She showed that it is very probable that elements of atomic number 93 and 94 are both formed in the process. Dr. M. L. Oliphant described some recent work carried out in Cambridge, while Goldhaber showed that the mean free path in paraffin of the neutrons produced by the photo-electric disintegration of deuterium does not have the value predicted by the accepted theoretical picture of the interactions between neutrons and protons.

Uhlenbeck described how the modification of the Fermi theory of β-decay, proposed by Uhlenbeck and Konopinski, is in good accord with experiments on the energy distribution of β-particles from both electron and positron emitters of low atomic number. Richardson gave similar evidence in the case of β-emitters of high atomic number.

The general impression left by the conference was that progress in experimental research on the atomic nucleus is very rapid, but that the advance in the theoretical description of the new results is much slower. This is due largely to inadequate theories of the interaction forces between particles of high energy separated by small distances, which are of fundamental importance in the region of the nucleus.

Recent Advances in Wool Research

SEVERAL papers read at the Annual Conference of the Textile Institute held in London on June 3–5 dealt with wool and its characteristics.

Dr. A. B. Wildman, biologist of the Wool Industries Research Association, discussed estimations in the fleece of important wool characteristics, such as fineness variability, length, fleece density and kemp proportion. Emphasis was laid on the necessity for devising speedy and accurate methods of fleece analysis, in order that the relative merits of fleeces from breeders' flocks and from experimental sheep could be accurately measured. A historical résumé of earlier work was given, indicating that conflicting results were often due to lack of representative sampling methods. The author gave an account of his methods, which are subject to statistical control, in commencing analyses of thoroughly sampled fleeces. These investigations are intended to show the kind of variations occurring in fleeces of different types of sheep, and represent an essential prerequisite in the evolution of suitable methods for quality determination.

The quality of a fleece may be modified by exposure to light, air and water. This is attributed by Dr. J. B. Speakman, of the University of Leeds, in a paper on "The Reactivity of the Sulphur Linkage in Animal Fibres", to the oxidation of intact disulphide bonds or their hydrolysis products. More regulated changes of this nature occur in the milling, carrotting, crabbing and blowing processes. Dr. Speakman produced evidence to show that the cystine disulphide cross-linkage is more susceptible to hydrolysis in the stretched than it is in the unstretched fibre. He also showed that the contractile power of treated stretched fibres is dependent on the extent of the hydrolysis of the cystine disulphide cross-linkages, which vary with the *p*H value of the solution in which the fibre is treated.

Raw wool may contain fifty per cent of its weight of grease, suint, dirt and vegetable matter. Its cleaning is, therefore, an intricate process, and was the subject of two papers from the Wool Industries Research Association. Some of the fundamental principles of washing raw wool with solutions of soap and soda were dealt with by Dr. H. Phillips, who showed that the *p*H values of the detergent solutions used influence their wetting and emulsifying powers, and the stability of the emulsions which they form. Variations in the relative proportions of the different impurities in raw wool, caused by variations in the health of the sheep and the climatic conditions, have to be met by alterations in the washing process, which can only be foreseen when the process is under scientific control. Inherent weaknesses in the process are the effect of the alkali used on the wool and the incomplete removal of vegetable matter.

Dr. S. Townend described the frosted wool process, recently developed in the United States, by which it is claimed that large quantities of vegetable matter and grease can be removed from raw wool without subjecting it to alkaline solutions. The wool is cooled to −40° F., and the frozen grease and vegetable matter are broken up and removed by mechanical treatment. The process removes more vegetable matter than the normal washing process, but the finer qualities of wool still require carbonising after treatment. The grease content of the wool cleaned by this process is also relatively high, and for certain purposes the wool has to be washed with soap and soda.

Chemical Engineering Congress of the World Power Conference

H.R.H. THE DUKE OF KENT, in opening on Monday, June 22, the First International Chemical Engineering Congress at the Central Hall, Westminster, and welcoming delegates and members from thirty-seven countries, said: "Proud as each country is of the achievements of her great scientists and inventors, their work once done becomes international and contributes to the well-being and happiness of every race". The Right Hon. Viscount Leverhulme, in his presidential address which followed, dealt with the subject of chemical engineering and stated that the conception of holding an international congress of this kind was due to the late Sir Frederic Nathan, and that the development of that ideal into the present meeting was brought about by the World Power Conference.

About 120 papers from fifteen different countries were presented for discussion, whilst the membership numbered 850, comprising about 350 representatives from thirty-six overseas countries.

Two technical sessions were held before lunch and two in the afternoon on Tuesday, June 23, and Friday, June 26, but as visits to colleges, research institutions and works in and around London had been arranged for Wednesday afternoon and Thursday afternoon, the technical sessions on these days were limited to the forenoon.

Since chemical plant may have to resist corrosive conditions and may have to withstand high temperatures and/or high pressures, both the material of which it is constructed and the method of fabrication are important factors to the chemical engineer. It was therefore not surprising that the papers and discussions at the first two sessions on Tuesday morning were devoted to materials of construction. At the first of these, eight papers were presented dealing with ferrous metals and their alloys designed to resist heat, rust and acid corrosion, the forging of autoclaves and vessels for withstanding liquids at high temperatures and pressures. Nor was cast iron omitted, for included in this section were papers showing the result of recent research work on this material and its application in chemical industry, as well as others on the prevention of corrosion in underground pipe lines made of ferrous metals. The following session covered a much wider field since it contained papers on refractory materials, stoneware, plastics, rubber and such lesser known fibres as jute, coir, and sisal, as well as non-ferrous metals and their alloys, and their application in the construction of chemical plant.

Separation in the chemical industry is such a wide subject that at the third session, after lunch, the papers ranged from the theory of coal-washing through the recovery of benzol and the removal of carbon monoxide from town's gas to the production and treatment of road tars and to problems connected with the distillation of absolute alcohol, fractionation of heavy oils, modern cracking processes and graphical calculations relating to plate columns. Included in this section were other papers on filtration, recent developments in evaporation, crystallization, solvent extraction and drying.

The fourth session, which followed immediately, contained several papers relating to some interesting aspects of size reduction, among which was one describing a plant wherein low-grade fuel such as lignite can be pulverized and fired into the furnace of a boiler in one process, the boiler operating at a very high efficiency.

Another group of papers in this session considered electro-metallurgical and electro-chemical industries, as well as the electrolytic treatment of water for the prevention of corrosion and boiler scale and methods of removing small quantities of iron from soluble aluminium salts, the pasteurization of liquids, anodic oxidation of aluminium and arc welding of low carbon steels.

At the first session on Wednesday morning, the subject under discussion was destructive distillation, in which in addition to a paper on the underground gassification of coal, there was a number of papers on the problems connected with the manufacture of water gas and town's gas from lignite and similar fuels, as well as several papers on the various aspects of the development which has taken place in the gas industry in various parts of the world.

With the rapid growth of large industrial units, the disposal of waste material, whether solid, liquid or gaseous, has become a pertinent and pressing problem to the chemical engineer. It formed the subject of several papers at the next session. Coupled with this series were other papers which showed the recent developments which have taken place in the preparation and treatment of lubricating oils.

Within comparatively recent times, considerable attention has been directed towards the use of high pressures in the synthesis of organic compounds, the hydrogenation of tar and tar distillates and gaseous liquid phase reactions. The first session on Thursday morning was devoted to this subject. Included with this group of papers was one on the use of high vacua.

Few chemical engineers escape the problem of considering the transmission of heat to or the removal of heat from the product at one or more stages in the course of its manufacture. The importance of this subject therefore demanded the attention of the members during the second session on Thursday morning, when papers dealing with the evaporation of solutions liable to be affected by high temperatures, and the use of waste heat for low-temperature evaporation as well as methods by which waste heat may be recovered from intermittent sources, were under discussion.

The attendance and discussion which followed the report upon the papers on Friday morning dealing with the training of a chemical engineer indicated how this subject has been claiming the attention of both industrialists and teachers in America, Austria, Canada, France, Germany, Great Britain, Japan and the U.S.S.R.

In the session which followed were papers from Germany, Great Britain and the United States of America on administration, safety and welfare, and the statistical duties which fall to the lot of the chemical engineer in industry. These papers show how the countries concerned are taking precautionary measures to reduce accidents and occupational risks attendant upon chemical industry, and the factors which influence the choice of site for a works and the cost of the product.

Trend of development was the title allotted to the first session on Friday afternoon, at which papers were presented on a variety of subjects in which amongst others are those relating to water treatment and softening, fumigation, developments in the sulphuric acid industry and the production of concentrated fertilizers from poor phosphates. Although the papers in this group deal with many subjects, their importance to the technical worker cannot be denied, since they consider problems arising in many industries.

The organization of research stations both of a public and private character and the part which fundamental research must play in industrial organizations were the subjects of some of the papers presented at the last session, which also included other papers on rapid methods of determining the standard of the product, the standardization of chemical apparatus and its future development, as well as a number of other aspects of interest to the chemical engineer.

Sir Harold Hartley, chairman of the International Executive Council of the World Power Conference, presided on Saturday morning at the closing meeting of the Congress, at which various reports were presented. Thanks were also tendered by numerous speakers to the various committees and officers, and a striking tribute not only to the success but also to the utility of the Congress was given when it was announced that an invitation had been received from the German National Committee to hold a second International Congress on Chemical Engineering in Berlin in 1940.

Oceanic Macroplankton of the *Dana* Expeditions*

DR. P. JESPERSEN has compared the amount of macroplankton in the various waters investigated by the Carlsberg Foundation's Oceanographical Expedition round the world in 1928–30. Volume determinations were made of 2231 pelagic hauls, distributed in eight regions—North Atlantic and Caribbean Sea, Pacific and Tasmanian Sea, Indo-Malayan region, waters west of Sumatra, Indian Ocean, South Atlantic, Straits of Gibraltar and adjacent waters, and the Mediterranean.

The paper deals solely with the purely quantitative side of the macroplankton as a whole, the only exception being a determination of the fish and fish fry of the different water layers in the regions of the Pacific: otherwise only occasional notice is taken of what organisms may be dominant—so far as volume is concerned—in the composition of the plankton. It is usually the salps which are thus noted, sometimes siphonophores, *Sagitta*, euphausiids and decapods.

A comparison of the microplankton on the two sides of the Panama Isthmus shows a very great difference. Thus in the upper water layers (50–100 metres wire) the quantity is greater in the Caribbean Sea, but in all deeper hauls the volumes are very much greater in the Gulf of Panama. It is shown that in layers corresponding to hauls with 300–600 metres wire the amount of macroplankton in the Gulf of Panama is about twice the amount in the Caribbean Sea, and in depths corresponding to hauls with 1,000–3,000 metres wire the quantities of plankton are six to eight times larger in the Gulf of Panama than in the Caribbean Sea. The remarkably rich plankton fauna in the deeper waters of the Gulf of Panama is of peculiar interest, as nowhere else in the areas of the Pacific, Indian Ocean or the South Atlantic investigated is anything like such large quantities met with. It is only in the North Atlantic at about 30° N. that corresponding quantities of plankton are found in the deeper layers.

It is characteristic of the plankton fauna of the Gulf of Panama that it is considerably richer in the deeper than in the surface layers, a condition quite unique, since at all other places in the regions investigated the quantities of plankton are greatest in the upper layers. It may be said that, on the whole, the quantity of macroplankton in the deeper layers (hauls with at least 1,000 metres wire) is comparatively small and fairly uniform in most of the tropical and temperate oceanic regions. The one exception is the Gulf of Panama, where we find a remarkably large quantity of plankton in the deeper layers.

Educational Topics and Events

Birmingham.—The degree of D.Sc. has been awarded to the following: C. T. Barber, for published papers dealing mainly with the geology of certain districts of Burma, with particular reference to natural gas and oil resources; Mabel E. Tomlinson, for papers in the *Quarterly Journal of the Geological Society* on river terraces of the lower valley of the Warwickshire Avon, and on the superficial deposits of the country north of Stratford-on-Avon, and a paper on the drifts of the Stour–Evenlode watershed (*Proc. Birmingham Nat. His. and Phil. Soc.*); G. D. Elsdon, for published work on edible oils and fats, analysis of drugs and chemicals, and numerous papers on chemical investigations in subjects relating to public health.

Cambridge.—G. C. Evans, of St. John's College, has been appointed to the Frank Smart University studentship in botany, and Dr. L. E. R. Picken of Trinity College to the Balfour studentship.

A grant of £25 has been made from the Balfour Fund to J. D. Robertson, of St. John's College, for research on the calcareous skeletons formed by marine animals.

Glasgow.—The Bellahouston Bequest Fund Trustees have made a grant of £5,000 towards the cost of erection of the new chemistry buildings.

Prof. Gilbert Cook, professor of mechanical engineering, King's College, University of London, has been appointed regius professor of civil engineering and mechanics in succession to the late Prof. J. D. Cormack.

Prof. J. Shaw Dunn, St. Mungo-Notman professor of pathology in the University, has been elected professor of pathology in succession to Sir Robert Muir, who has retired.

Dr. H. B. Cott has been appointed lecturer in zoology.

The Gibson Lecture for 1936–37, on the history of mathematics, will be delivered by Dr. John Dougall at the Royal Technical College, Glasgow.

Leeds.—Dr. Archibald Durward has been elected to the chair of anatomy in the University in succession to Prof. J. Kay Jamieson, who has resigned. Dr. Durward has been a member of the anatomical staff of University College, London, since 1931; he was educated in New Zealand, and held appointments for six years in the Anatomy Department of the University of Otago.

Mr. Frank Parkinson, of Messrs. Crompton Parkinson, Ltd., Manufacturing Electrical Engineers, has placed a fund of £50,000 in the hands of the Council on loan, free of interest, which is to become the absolute property of the University after seven years. The gift is to be used as a Scholarship Endowment Fund, to be applied to the foundation of research fellowships or scholarships for graduates and scholarships or grants for undergraduates. Pending receipt of interest from the fund, Mr. Parkinson has offered a sum up to £1,500 to be granted in scholarships during the first year.

Liverpool.—The following appointments have recently been made: Dr. A. G. Walker, lecturer in the Department of Pure Mathematics, in succession to Dr. Haslam-Jones, who has been elected a fellow of Queen's College, Oxford; Dr. H. R. Hulme, lecturer in the Department of Applied Mathematics, in succession to Dr. G. C. McVittie, who has been elected to a readership at King's College, London; Dr. C. J. Williams, Leverhulme Foundation lecturer in the Department of Physics, in succession to Dr. Norman Feather, who has been elected to a fellowship at Trinity College, Cambridge.

London.—The title of reader in neurological anatomy in the University has been conferred on Miss U. L. Fielding in respect of the post held by her at University College.

The degree of D.Sc. in botany has been conferred on Mr. D. G. Catcheside, a recognised teacher at King's College.

University postgraduate travelling studentships of the value of £275 for one year have been awarded to Dr. C. J. B. Clews (Queen Mary College), and K. Stewart (Imperial College—Royal College of Science). Dr. Clews proposes to do further research in X-rays under the direction of Prof. K. M. G. Siegbahn at the University of Uppsala, and Mr. Stewart intends to study the chemical reactions in the electric discharge under the supervision of Prof. P. Harteck at Hamburg. University postgraduate studentships of the value of £150 for one year have been awarded to W. A. Cowdrey (University College); A. J. P. Crick (King's College); J. A. Downes (Imperial College—Royal College of Science); J. Gold (University College); A. M. Houghton (King's College); Margaret M. Jamison (Bedford College); L. J. Jolley (University College); J. Lawton (University College); and the studentship awarded to Joel Hirschfield in 1935 has been renewed for a second year.

Oxford.—At Encænia on June 24, the honorary degree of D.Sc. was conferred on Prof. E. D. Adrian, Foulerton research professor of the Royal Society.

Sir George Macdonald has been elected an honorary fellow of Balliol College.

W. E. Grimshaw, Corpus Christi College, has been granted the degree of D.Sc. for his work on plastico-viscous deformation and on combustion problems.

Dr. W. Stephenson, of the Psychology Department, University College, London, has been appointed assistant director of the newly-founded Institute of Experimental Psychology (see p. 14 of this issue).

St. Andrews.—On June 26, the honorary degree of LL.D. was conferred on the following, among others: Prof. E. Waymouth Reid, emeritus professor of physiology, University College, Dundee; Prof. J. E. Littlewood, Rouse Ball professor of mathematics in the University of Cambridge; Mr. David Anderson, consulting engineer, London.

The degree of D.Sc. has been conferred upon H. Greene, for a thesis entitled "Investigations on the Soil of the Eastern Gezira, Anglo-Egyptian Sudan", and on G. J. Robertson for his investigations on Walden inversions in the sugar group.

The fifth Congress of the Universities of the British Empire will be held in Cambridge on July 13–17, under the presidency of the Right Hon. Stanley Baldwin. Further information can be obtained from the Secretary, Universities Bureau of the British Empire, 88a Gower Street, London, W.C.1.

Science News a Century Ago

Patent Laws of the United States

THE act of Congress establishing the United States Patent Office under a commissioner was passed on July 4, 1836, and from that time American patents have been numbered serially. The issue of patents was provided for in the first article of the Constitution, where Congress was given power "To promote the progress of science and useful arts by securing for limited times to authors and inventors the exclusive rights to their respective writings and discoveries", and the first act of Congress specifying how patents were to be issued was passed on April 10, 1790. The act of July 4, 1836, was the outcome of a Select Committee of Congress appointed "to take into consideration the State and Condition of the Patent Office and the laws relating to the issuing of Patents for New and Useful Inventions and Discoveries". In the report of this Committee, it was stated that the average number of patents issued annually from 1790 until 1800 was but 26; from 1800 until 1810 the average was 71; from 1810 until 1820 it was 200 and for the ten years previous to 1836 it had been 535. The whole number of patents issued under the laws of the United States up to March 31, 1836, was 9,731. This was more than double the number which had been issued in France or England during the same period.

The Entomological Society

AT a meeting of the Entomological Society held on July 4, 1836, the Rev. F. W. Hope, president, being in the chair, Count Gotthelf Fischer de Waldheim, of Moscow, was elected an ordinary foreign member of the Society. The secretary made some observations upon an extensive series of specimens, represented by anglers as their artificial flies, collected by Mr. Ronalds for his work entitled "The Fly-fisher's Entomology". The president also made some observations upon the system adopted in North America whereby two crops of silk are produced in a season, as described by Mr. Kenrick in his work lately published upon that subject in the United States. (*Athenæum.*)

The Rev. Frederick William Hope (1797–1862) who was elected president of the Entomological Society in 1835 and 1846 was a graduate of Christ Church, Oxford. He presented his collection of insects and prints to the University and was the founder of the professorship of zoology.

Lyell and Mantell

WRITING on July 6, 1836, from Kinnordy, Kirriemuir, N.B., to Mantell at Brighton, Lyell said: "Here I am rusticating in a very beautiful country, not too hot, but with weather much like a fine English spring. I am now and then devoting some stray hours to my 'Elements', like Buckland's 'Bridgewater' long promised—but not yet reviewed, thank heavens. I have received a very pleasant letter from Alexander Burnes, who has returned to Cutch and re-examined the delta of the Indus. He reports that the submerged tract which sank in 1819 is *in statu quo*. He has sent me off some Cutch secondary fossils, ammonites, belemnites, etc. His letter came in nine weeks per steamer from Cutch! A letter from Dr. Silliman informs me that my 'Principles' are being printed in Philadelphia, and nearly ready. John Murray was in hopes he had reduced the price so as to prevent this happening."

Darwin at St. Helena

SAILING from Mauritius on May 9, 1836, H.M.S. *Beagle* called at the Cape of Good Hope and on July 8 arrived at St. Helena. "The next day," Darwin wrote in his Journal, "I obtained lodgings within a stone's throw of Napoleon's tomb: it was a capital central situation, whence I could make excursions in every direction. During the four days I stayed here, I wandered over the island from morning to night, and examined its geological history. My lodgings were situated at a height of about 2000 feet. . . . Near the coast the rough lava is bare; in the central and higher parts, feldspathic rocks by their decomposition have produced a clayey soil which, where not covered by vegetation, is stained in broad bands of many bright colours. . . . Beneath the upper and central green circle, the wild valleys are desolate and untenanted. Here, to the geologist, there are scenes of high interest, showing successive changes and complicated disturbances. According to my views, St. Helena has existed as an island from a very remote epoch; some obscure proofs, however, of the elevation of the land are still extant. I believe that the central and highest peaks form part of the rim of a great crater, the southern half of which has been entirely removed by the waves of the sea: there is, moreover, an external wall of black basaltic rocks, like the coast mountains of Mauritius, which are older than the central volcanic streams."

Trans-Atlantic Steam Navigation

IN July 1836 the books of subscription were opened of the British and American Steam Navigation Company, the first of the pioneer companies to construct a steam vessel for regular work on the North Atlantic. The company had been formed through the exertions of the American lawyer and business man Junius Smith (1780–1853). In 1832–33 he had crossed from England to the United States and back again by sailing packets. His outward journey had taken 54 days, his return journey 32 days, and it was these passages which led to his determination to promote steam navigation across the Atlantic. At first he met with no encouragement, but finally with the aid of Macgregor Laird (1808–61), the African explorer, he was able to float a company. When sufficient money was forthcoming, a contract for the *British Queen* was made with Messrs. Curling and Young, of Limehouse, and Smith wrote to his New York correspondents: "I have the pleasure to inform you that the Directors of the 'British and American Steam Navigation Company' have contracted for the building of the largest and intended to be the most splendid steamship ever built expressly for the New York and London trade. She will measure one thousand seven hundred tons, two hundred feet keel, forty feet beam, three decks and everything in proportion. She will carry two engines of two hundred and twenty-five horse-power each, seventy-six inch cylinder, and nine feet stroke. The expense of this steam frigate is estimated at £60,000."

The *British Queen* was the first steam vessel constructed expressly for the Atlantic trade; but she did not make her first passage until July 1839, by which time the *Sirius*, *Great Western*, *Royal William* and *Liverpool* had all made passages to the United States and back.

Societies and Academies

Edinburgh

Royal Society, June 1.

E. M. Anderson: The dynamics of the formation of cone-sheets, ring-dykes, and caldron-subsidences. Cone-sheet and ring-dyke systems are best known in Scotland and Northern Ireland, but are not confined to these districts. Cone-sheet formation may be explained by an excess of pressure, and ring-dyke formation by a defect of pressure, in an underlying magma basin, with a more or less dome-shaped roof. Solutions of the equations of equilibrium corresponding to certain shapes of basin have been found by the author.

J. B. Simpson: Fossil pollen in Scottish Tertiary coals. Lignites of early Tertiary age from Ardnamurchan and Mull, treated with Schulze's solution and alkali, yield a residue rich in well-preserved pollen. By this means, twenty genera of plants have been identified so far, including several not previously recorded as Scottish fossils. Of the gymnosperms *Cedrus* pollen is most abundant; *Abies* also has been noted. Dicotyledons include *Alnus, Engelhardtia, Magnolia, Planera*, five of the Asiatic genera of the Hamamelidaceæ and the Madagascan genus *Dicoryphe*. The present-day eastern Asiatic flora shows marked affinities with this ancient Scottish flora. (See also Nature, Feb. 22, p. 321.)

H. P. Donald: On the suppression of Tangled in *Drosophila pseudo-obscura*. An additive interaction of genes causing gaps in the venation with one causing extra tangled venation has shown that the phenotypic manifestation of a gene is no indication of its capacity to suppress the effects of another, and that genes with a recessive manifestation may have a dominant suppressing action which is not localized to the regions where the gene itself has visible effects.

H. W. Turnbull: The revised prepared system of the quadratic complex. This deals with one aspect of the invariant theory of quadratic forms in six variables by supplementing a previous communication in 1928 to the Society.

W. Ledermann: On singular pencils of Zehfuss, compound and Schläflian matrices. The paper is concerned with obtaining the canonical form of pencils of matrices related to two given matrices. The types considered are the compound, power and product transformations. Quite recently Roth, Aitken and Littlewood have dealt with the non-singular cases of these. The present paper completes the work of these authors by enumerating and solving all the outstanding singular cases.

Paris

Academy of Sciences, May 25 (*C.R.*, 202, 1725–1824).

Dimitri Riabouchinsky: Comparative research on the aerodynamics of small and of large velocities.

Jacques de Lapparent: The formula and structural scheme of attapulgite.

Daniel Dugué: Certain modes of convergence of laws of estimation.

Serge Finikoff: Some conjugated networks.

Constantin Dramba: The singularities of the restricted problem of three bodies.

Eugène Leimanis: The solutions of a differential system in the neighbourhood of a singular multiplicity.

A. D. Michal and E. W. Paxson: The differential in linear abstract spaces with a topology.

Florin Vasilesco: The generalized problem of Dirichlet and its relations with *balayage*.

Raymond Valtat: A calculating machine based on the use of binary numeration.

Maurice d'Ocagne: Remarks on the preceding note of Raymond Valtat.

Paulino Castells Vidal: A machine for resolving systems of linear equations.

Joseph Chalom: Reaction pumps.

A. Toussaint and S. Pivko: Guided plane stream. The influence on the aerodynamical characteristics of supporting wings.

Louis Breguet: The possibilities of speed and radius of action of gyroplanes. From a theoretical study it is concluded, that in addition to the advantages of vertical take-off and alighting, gyroplanes (helicopters) should, other conditions being equal, have a higher velocity and greater radius of action than ordinary aeroplanes.

Max Serruys: The influence of turbulence on the polytropic coefficient of expansion in petrol motors.

Stéphan Serghiesco: The formula of Fresnel in a corpuscular theory of light.

Georges Durand: The application of the mass-luminosity relation to the visual double stars.

Pierre Vernotte: The theoretical dimensions of the cellular vortices of Bénard.

Roger Julia and Jean Fallou: The extension of the properties of the quadripole to the most general balanced polyphase systems.

André Michel: The conditions of demagnetization of rhombohedral ferric oxide.

Roger Servant: Measurements of double refraction in the extreme ultra-violet. The measurements of P. Sève were given to 2400 A.; the author extends these to about 1860 A. and intends to extend the work in the Schumann region up to the extreme limit of transparency of the crystalline specimens.

Léandre Capatos and Nicolas Perakis: The magnetic study of the mixed crystals of divalent copper and silver. Measurements made with the complex compounds of pyridine with persulphate of copper and of silver, and of mixed crystals of the type $(Ag_xCu_y.4Py)S_2O_8$, where x and y vary from 0 to 1.

Georges Ahier: Christiansen filters. These light filters consist of a cell containing powdered glass rendered transparent by immersion in a liquid of the same refractive index. For the liquid, solutions of bromomercurate or iodomercurate of potassium and barium fulfil the required conditions better than the organic liquids usually employed.

Victor Lombard, Charles Eichner and Maxime Albert: The permeability of palladium to hydrogen. Loss of the diffusing power of pure palladium under the action of temperature. Regeneration of the poisoned palladium. A sheet of pure palladium, after exposure to a temperature of 500° C. or higher, suffers a marked diminution in its permeability to hydrogen. Oxidation in a current of air at 500° C. with subsequent reduction in hydrogen below 140° C. restores the permeability almost to the original figure.

Mlle. O. Hun: The determination of the total hydration of the ions of potassium iodide, by the cryoscopic method.

AUGUSTIN BOUTARIC and MLLE. PAULETTE BERTHIER: The mechanism of the ascent of hydrosols and of coloured solution through porous bodies.

MLLE. LUCIENNE CHAUMETON: The silver salts of amidosulphonic acid.

OSIAS BINDER and PIERRE SPACU: The action of malonic acid on cobaltidichloro-*trans*-diethylenediamine chloride.

ANDRÉ BOULLÉ: Calcium metaphosphates and pyrophosphates.

PAUL LACOMBE and GEORGES CHAUDRON: The mechanism of the decomposition of aluminium-magnesium solid solutions.

HENRI FOURNIER: The application of the methods of micro-chemical analysis to the study of the corrosion of light aluminium alloys. Two alloys were studied, duralumin and an aluminium alloy with 8 per cent magnesium. The amounts of aluminium determined were of the order of micrograms.

ROGER PAJEAU: The action of bromine in excess on some benzene derivatives in the presence of beryllium bromide.

LOUIS DANGEARD: Study of the oolitic limestones by staining and decalcification. Staining followed by slow decalcification brings out details of certain micro-organisms concerned in the precipitation of calcium carbonate and in the evolution of a large number of ooliths.

THÉODORE MONOD: New data on the structure of the western Sahara.

MARCEL GAUTIER: The stratigraphy of the region of Nemours (Algeria).

ARMAND RENIER: The structural plan of the subsoil of Belgium, chiefly from mining operations.

EMILE BELOT: Geophysical and mineralogical consequences of the hypothesis that the earth has had a vortex tube for origin.

HUBERT GARRIGUE: New results on the light of the night sky.

HENRI MARCELET: The presence of hydrocarbons in the product removed by deodorization in the refining of arachis oil.

PAUL RIOU, GÉRARD DELORME and HORMISDAS: The distribution of manganese and iron in the pines of Quebec.

ETIENNE FŒX and MAURICE LANSADE: The pathogenic action of a form of ***Fusarium oxysporum*** isolated from the potato.

DOMINGO M. GOMEZ: The decrease of arterial pressure as a function of time. Its determination in man by a piezoelectric method.

LÉOPOLD NÈGRE, ALBERT BERTHELOT and JEAN BRETEY: The action of ethyl stearate on the evolution of experimental tuberculosis of the guinea pig. In guinea pigs submitted to the action of ethyl stearate, the lesions appear later than in untreated animals.

PIERRE DRACH: The water absorbed in the process of exuviation; fundamental data for the physiological study of moulting. Definitions and quantitative determinations.

MME. VÉRA DANTCHAKOFF: Some factors determining secondary sexual characters.

MLLE. N. CHOUCROUN: Superficial electrification, a specific character of bacteria.

Vienna

Academy of Sciences, April 23.

GÜNTHER LOCK and GÜNTHER NOTTES: Derivatives of 3,5-dimethoxybenzaldehyde (5). The Cannizzaro reaction. In the chlorination, bromination and nitration of 3,5-dimethoxybenzaldehyde, only the hydrogen atom next to the aldehyde group undergoes substitution.

OTTO DISCHENDORFER and AUGUST VERDINO: Condensation of benzoin and thymol (2). Determination of the constitution of the nitration products of 4-methyl-7-*iso*propyl-2,3-diphenylcumarone.

MAX PESTEMER and FRIEDRICH MANCHEN: Ultraviolet absorption of some aromatic hydrocarbons (4). Constitution of hexahydropyrene.

OTTO REDLICH and WALTER STRICKS: Raman spectra of *o*-dideuteriobenzene and *N*-deuteriopyrrole.

ANTON KAILAN and SIEGFRIED ROSENBLATT: Velocity of esterification of alcohols in formic and acetic acid, and of formic acid in tertiary butyl alcohol.

L. ZECHMEISTER and L. v. CHOLNOKY: Thirty years of colour science.

R. JAGITSCH and A. MASCHIN: Reactions in the solid state (2). A study of the formation of copper ferrite by the Hahn emanation method.

LUDWIG ECKHART: The line of striction of a hyperbolic ruled surface.

HUGO BONDY and VIKTOR VANICEK: Relative abundance of potassium and lithium isotopes and the emission of alkali ions from glass melts. The abundance ratios of potassium and lithium isotopes from different glass melts were found to be ^{39}K/^{41}K = 14·1 and ^{7}Li/^{6}Li = 12. If a glass melt contains several alkali metals, the emission at low temperatures is due almost entirely to the element with the lowest ionization potential, and the surface of the melt undergoes impoverishment of the elements of higher ionization potential.

ERWIN FISCHER COLBRIE: Nuclear disintegration by a radium B + C source (2). Nitrogen. Protons liberated by radium C′ α-particles from nitrogen are found, by absorption measurements, to form two groups of different energy.

ADRIAN SCHUSTER: Tenebrionid (Col.) finds of Prof. Franz Werner and Dr. Otto Wettstein in the Greek Ægean Isles and in the Italian Dodecanese in 1934 and 1935.

E. STEINACH, H. KUN and O. PECZENIK: Recent researches on the action of sex hormones. (1) Castrated male rats do not show hyperæmia of the brain on injection with androsterone unless this contains œstrogenic substances. (2) The minimum dose of free male hormone required by castrated rats before copulation with a female occurs is reduced to nearly a third by the injection of female hormone. (3) The male organism is capable of converting excess male hormone into a substance with œstrogenic properties.

KARL KARAS: Kinematics of an expanding sheet.

April 30.

F. E. SUESS: Interpretation of the occurrence of pumice stone at Kofels in Ötztale. It is suggested that this occurrence and the peculiarities of the surrounding terrain are best explained as the result of the impact of a large meteorite.

FRITZ LIEBEN and BELLA BAUMINGER: The behaviour of sugars and formic acid in the presence of oxidizing bacteria.

RICHARD SCHUMANN: The moon, sun, and variations of latitude (1).

Forthcoming Events

Friday, July 10

ASSOCIATION OF APPLIED BIOLOGISTS.—Summer Meeting to be held at the Royal Horticultural Society's Gardens, Wisley, Sussex.

Saturday, July 11

BRITISH MYCOLOGICAL SOCIETY, at 11.45.—Annual Phytopathological Meeting to be held at the University of Bristol Research Station, Long Ashton, near Bristol.

MUSEUMS ASSOCIATION, July 6–10. Forty-seventh Annual Conference to be held at Leeds.

July 7, at 10 a.m.—Sir Eric Maclagan: Presidential Address.

SOCIETY OF CHEMICAL INDUSTRY, July 6–10. Fifty-fifth Annual Meeting to be held at Liverpool.

July 7, at 10.45.—W. A. S. Calder: "The Chemist as World Citizen" (Presidential Address).

July 8, at 11.30.—Sir Robert Mond: "Works as I have seen them grow" (Messel Lecture).

DECHEMA (Deutsche Gesellschaft fur Chemisches Apparatewesen), July 9–10. To be held in Munich.

GENERAL ASSEMBLY OF THE INTERNATIONAL ASTRONOMICAL UNION, July 10–17. To be held in Paris.

Research and Finance

THE Parliamentary Science Committee has prepared a memorandum on the development and finance of the Department of Scientific and Industrial Research, including research associations. The memorandum is based upon a preliminary memorandum previously formulated by a joint committee of the British Science Guild and the Association of Scientific Workers. This joint committee may be regarded as the forerunner of the Parliamentary Science Committee, which is now, however, an independent body supported by a number of scientific institutions.

It is, of course, all to the good that a body, the membership of which embraces many distinguished scientific workers as well as industrialists, should devote its thought and energy to the question of how scientific research, and, perhaps, more especially, industrial research, in Great Britain should be developed and financed; but, equally of course, the Parliamentary Science Committee cannot claim to speak with paramount authority on this subject. Its views are its own, and the memorandum under consideration is to be regarded as its serious and constructive contribution to the general question stated above. The memorandum, when it is published in its final form, will no doubt be carefully considered, as it will deserve to be considered, by the Government and by such bodies as the Advisory Council of the Department of Scientific and Industrial Research, the Conference of Research Associations, the British Association, the Royal Society, and, it may be hoped, the Federation of British Industries—all of which having a direct interest in the subject matter of the memorandum, and each capable of contributing its own special knowledge and experience. We have been allowed to peruse the memorandum in its present form, and it may help to a constructive consideration of the very important questions raised if we endeavour to summarize briefly its argument and recommendations and to comment on them. We shall confine ourselves to the question of industrial research.

The memorandum starts by accepting as unquestionable the value of scientific research applied to the methods of industrial production, and pays ungrudging tribute to the work done by the research associations—numbering now some twenty—established under the scheme of the Department of Scientific and Industrial Research. "From six research councils only at the expense of less than £400,000 in all have come researches which have made possible a saving of £3,200,000 per annum. The aggregate saving from the work of all the Research Associations must be several times this sum and must represent a return on money invested of between 500 and 2,000 per cent."

Notwithstanding the demonstrated financial benefits that have resulted from scientific research, the problem of how to finance industrial research on a scale adequate for its maintenance and development is still acute. The real value of scientific research, whether pure or applied, is spread widely and can be financed only by finding an equally comprehensive basis for the collection of the necessary funds. Moreover, since one of the primary requirements of organised scientific research, and especially of industrial research, is that it should be prosecuted in a considered direction for a number of years, finance must provide for continuity.

The memorandum reviews briefly the methods adopted during the last eighteen years to finance the industrial research associations. At first it was intended that, after an initial period, the research associations should be entirely dependent on the support of their respective industries. In order to set the associations going and to convince industry of the value of research, a grant of £1,000,000 was made by Government, and this fund was used to supplement the subscriptions of the industries on a £ for £ basis over this initial period, which was first sanguinely estimated at five years. This plan proved impracticable; the five years' period was extended to ten years, but, as the exhaustion of the million fund coincided with the depth of the industrial depression, it was decided that Government assistance should be continued on a different basis.

The grants in aid of the research associations now come from the sums annually voted by Parliament for the Department of Scientific and Industrial Research, and a new system—"the datum line system"—has been instituted. Under this system the Department gives grants to the research associations on a £ for £ basis in respect of all subscriptions raised above a certain fixed datum, considered necessary for the upkeep of the association on a minimum basis of efficiency. The datum varies with the industry concerned, and there is an upper limit to the Government grant, now fixed generally at three times the datum figure. Thus if the schemes were fully utilized, the relative share of the Government would be two fifths of the total income available for expenditure on research. Moreover, the principle of Government grants in aid of research is now, apparently, accepted as a permanent policy—at least as permanent as is, say, the principle of State aid for education.

The Parliamentary Science Committee's chief criticism of the existing system of finance is "the rapidly fluctuating amount of money available for research and the lack of provision for the steady development of scientific research in industry". Accordingly, the memorandum sets forth certain "proposals for finance". In effect, they are proposals for the permanent endowment of research. "The ultimate sources of money needed for research," the Committee states, "are Government and Industry," and it is suggested that *both* should contribute to provide this endowment.

Incidentally, we may point out here that, in the long run, Government money can come only from the pockets of the citizens and, therefore, ultimately, from industry. It may be convenient to speak of both Government and industry contributing, but it will be as well to keep in mind that in the real "ultimate sources" it is industry that will have to find the money. It will serve, however, to regard the contribution of industry to research as being the direct contributions of the individual firms concerned as members of the several research associations; and to regard the Government grant as being the indirect contribution of industry generally, in return for the fruits of research, of which the general consumer is in the long run the greatest beneficiary.

The Parliamentary Science Committee rejects the method of raising contributions from the several industries by a statutory levy (as is done, for example, in the case of the woollen industry) on the ground that "the effectiveness of the application of scientific research depends to a large extent on the voluntary character of the collaboration between industry and science". On the other hand, the Committee rejects the alternative system of voluntary contributions because it has "the double disadvantage of penalising those firms who contribute as against those who do not and affording an extremely irregular income for scientific research".

We think the Committee's objections to the method of raising funds for research by means of a statutory levy are sound. There may be a few industries in which it is practicable, but in many industries it would be impossible to decide which firms did and which did not fall within the ambit of the industry under levy. Moreover, it is certain that there would be widespread opposition to such a plan on the part of a very great number of industries. The need for voluntary collaboration between industry and science, if the application of scientific research to industry is to be effective, was recognized from the outset of the research associations' scheme, and was well stated in one of the early annual reports of the Department of Scientific and Industrial Research.

The argument that those firms which contribute to research associations are 'penalised' as against those who do not, seems to us entirely misconceived. Voluntarily subscribing member firms of research associations derive directly, from the research work carried out and in other ways, benefits which are not available to non-members. It is true that in the long run non-member firms must benefit, and that ultimately, as has already been pointed out, the consumer will be the major beneficiary, but at first and for a time the subscribing members of the associations must be benefited and not penalized as against non-members. This must be a recurrent advantage with each successive discovery or advance, and is the main reason why members pay their subscriptions.

The argument that the system of voluntary contributions affords "an extremely irregular income for scientific research" has substance, but it can easily be pushed too far. Some fluctuations of income are inevitable in all organizations, whether devoted to scientific research or not, that are dependent largely for their income on voluntary contributions. It may be doubted whether the fluctuations of income in the case of the research associations, due to the voluntary character of the contributions from industry, are so "extremely irregular" as is suggested. The real trouble is not so much the magnitude of the fluctuations in the income from subscriptions, but the fact that the general average of the contributions is much too low, as the memorandum of the Parliamentary Science Committee recognizes. In any event, the fluctuations of income present a problem to the research associations not essentially different in character or, possibly, in extent, from that which individual industrial firms and whole industries have from time to time to solve. If the average income were enough, the fluctuations could well be managed, as similar irregularities are managed in business, by the building up and utilization of adequate reserve funds. These funds could well serve to 'iron out' irregularities in income. Scientific organizations in particular may be trusted to understand the functions of a fly-wheel. It seems to us that the Parliamentary Science Committee is prone to make too much of a bogey of fluctuations in income.

Having thus rejected both the statutory levy and voluntary contributions, mainly because they yield a fluctuating income, the Parliamentary Science Committee reaches, by an almost naïve logic, the conclusions that it is necessary to find some way of converting variable contributions into a fixed income and that this can be done only by the endowment of scientific research. Its proposal is "to set up a fund derived both from Government and Industry to provide a steady income sufficiently large for the basic needs of scientific research and for its expansion at a definite rate". The Committee estimates the amount required to be between £30,000,000 and £50,000,000, which might be raised immediately or by successive grants of two, three or four million pounds annually for a number of years. It is suggested, however, that the most equitable way of raising the sum would be to make it a charge on the revenue derived from the new Customs duties, such a compulsory grant to scientific research being regarded as compensation to the consumer for the loss of a free market.

"Once a Government contribution was assured, there would be no corresponding necessity for a steady contribution from industry," though the memorandum envisages contributions to the endowment fund from other sources, such as royalties from patents for the results of the work of the research associations and from statutory or quasi-statutory bodies.

Out of the annual contributions, raised as just indicated, and the interest on the sum already invested, the memorandum proceeds to say, "the current expenses for scientific research could be met according to a budget determined for some years ahead. In the end it would be hoped that science would be able to depend entirely on the interest from the fund and thus become independent of contributions from Government or Industry, although they might be required if any new developments on a large scale appeared to be necessary."

Such, stated very briefly (but not, it is hoped, so briefly as to be misleading), are the main features of the argument and proposals of the Parliamentary Science Committee for the establishment of a fund of, say, fifty million pounds, for the permanent endowment of scientific research, more especially in relation to industry.

The plan, it must be admitted, is both simple and bold. To many, indeed, it will seem grandiose. It would be impossible within the limits of a single article to examine adequately the proposals of the memorandum. But let us take one cardinal point. On what grounds is it possible to justify the removal from all Parliamentary control and criticism of the administration of essentially national funds raised by authority of Parliament ? Suppose the argument to be applied to our national system of education, that, in order to secure stability and "to convert variable contributions into a fixed income", it must be permanently endowed and thus rendered independent of Government grants and, therefore, of Parliamentary control. What would be the likely response of Parliament or of the electors generally to such a proposal ? To put it bluntly, are the proposals of the Parliamentary Science Committee 'practical politics' ?

Again, suppose such a fifty millions fund to be raised from national resources for the permanent endowment of research. What is to prevent some future Chancellor of the Exchequer, in desperate straits to balance his budget, from raiding the research fund, as previous Chancellors have raided road funds or sinking funds? No Government can bind future Governments.

The question should be considered whether research could not better be permanently endowed by each research association building up its own reserve fund. A Chancellor of the Exchequer in a tight corner would find it more difficult to raid these several scattered 'nest eggs' than to pounce upon some big central fund. The Department of Scientific and Industrial Research should encourage the formation of such reserve funds by the research associations.

The root problem remains, of course, how to secure for the research associations increased financial support so as to give them assurance not only of life but also of an expanded and expanding life. We cannot enter into this question fully here, but one point may be stressed. It has already been pointed out that so-called "Government grants" to research associations are in the last resort the indirect contributions of industry. Government is prone to complain that industry is not making a sufficiently large direct contribution to research. Government has it in its power to increase the indirect contribution of industry by the simple device of increasing the Government grants in aid. Experience has shown that increased contributions from Government do lead to an increase in direct contributions from industry, not merely to the research associations as such but also to the individual research work of the firms concerned. Finally, we agree with the Parliamentary Science Committee that a great deal more might be done by means of organized education, publicity and propaganda to secure wider and increased financial aid for the research associations.

Theory of Elasticity

An Introduction to the Theory of Elasticity: for Engineers and Physicists. By Prof. R. V. Southwell. (Oxford Engineering Science Series.) Pp. ix+510. (Oxford: Clarendon Press; London: Oxford University Press, 1936.) 30*s*. net.

A CONSIDERABLE gap exists between the preparation in engineering mechanics which is usually given in engineering schools and the preparation required to read such fundamental books as A. E. H. Love's "Mathematical Theory of Elasticity" or Lord Rayleigh's "Theory of Sound". Owing to this gap, new developments in the theoretical sciences are very slow to find their way into engineering literature, and it sometimes happens that very powerful methods which could be utilized in solving engineering problems remain for many years without applications. A striking example of this situation is represented by Clerk Maxwell's important paper "On the Calculation of the Equilibrium and Stiffness of Frames" (*Phil. Mag.*, 27; 1864). In this very condensed paper a general method of analysis of statically indeterminate trusses was developed for the first time. Although the problem of handling statically indetermined structures is of great practical importance, Maxwell's solution of the problem remained unknown to engineers until ten years later, when the method was rediscovered by O. Mohr (*Z. Architekten- und Ingenieur-Vereins zu Hannover*, p. 223; 1874), and put in the form which is now largely used in our theory of structures. Another example is represented by Rayleigh's method of approximate solution of vibration problems, which is so extensively and skilfully used by Prof. R. V. Southwell in the book under notice. Although the method was developed more than fifty years ago, its incorporation into English engineering books is a recent development.

Modern development of engineering is in the direction of more and more intensive utilization of pure science in solving practical problems. A designer interested in problems of strength of machine parts or engineering structures can no longer be satisfied with semi-empirical formulæ of strength of materials, and very often must go into a more refined analysis of stress distribution which can be done only by using the theory of elasticity. Under these conditions, engineers at the present time are becoming more and more interested in advanced study, and the purpose of Prof. Southwell's book is to provide the necessary preparation in the theory of elasticity required for reading more advanced books in that field.

The first three chapters of the book deal with problems which are usually discussed in books on the theory of structures. The author, by using Hooke's law and the principle of superposition, develops such fundamental theorems as the reciprocity theorem and Castigliano's theorems. The importance of these theorems is illustrated by many interesting examples. There is given also a general proof of the principle of superposition which is based on the use of Hooke's law. However, since there are exceptional cases in which Hooke's law holds while the principle of superposition cannot be applied, it would seem more satisfactory simply to postulate the principle of superposition and limit the discussion to those problems where it holds. The third chapter of the book deals with 'self-strained' bodies and structures. These important problems are usually treated with great brevity in books on strength of materials, and engineers should be thankful to Prof. Southwell for his very complete presentation of this subject. Beginning with very simple problems, he finally develops the general theory for handling self-stressed systems and gives an original and very instructive proof of Castigliano's theorem of least work, which enables him to introduce an interesting discussion of Saint Venant's principle.

The following four chapters contain material usually treated in books on strength of materials. An elementary theory of stress and strain is given and also the application of this theory to problems of torsion and flexure. It seems that in this place also the Mohr circle might have been discussed advantageously, instead of postponing its presentation to a more advanced chapter on the general analysis of stresses. In discussing deflections of beams, Macaulay's method is given. On the Continent, it is usually called Saint Venant's method, since Saint Venant originated the special method of integration which reduces the deflection problem under various conditions of lateral loading to the determination of only two constants of integration. The last of these four chapters deals with more complicated problems of stress analysis, including a treatment of helical springs, beams on elastic foundations, crankshafts and an elementary theory of bending of plates. A very complete discussion of boundary conditions in the theory of plates is added to this chapter.

The next five chapters deal with the fundamentals of the theory of elasticity. The discussion begins with a general analysis of stress and strain which at once requires a more elaborate system of notations than was used in the earlier portion of the book. Beginners in theory of elasticity usually have difficulty with symbols, and would appreciate the use of a system of notation which can be applied both in elementary strength of materials and in the theory of elasticity. In a book attempting to bridge the gap between elementary strength of materials and the theory of elasticity, this unification of symbols seems doubly desirable. However, Prof. Southwell prefers to change his symbols at the beginning of the chapters on elasticity, and he adopts in these chapters the notations of Kirchhoff and Love. From the point of view of engineers and designers, it seems very desirable to have some unification of symbols used in the theory of elasticity, and perhaps it is time to do some work in this direction. However, Prof. Southwell is sceptical regarding the possibility of any international agreement in regard to symbols after so much has been written in this field.

In Chapters xi and xii, the general equations of the theory of elasticity are applied to such important problems as torsion and bending of prismatical bars (Saint Venant's problem), to two-dimensional problems, and to cases of axially symmetrical stress systems. The author gives not only the theoretical solutions of the problems, but discusses also various experimental methods of solution such as the soap film and photo-elastic methods, which in recent times have been developing so rapidly in connexion with technical applications of the theory of elasticity.

The last two chapters of the book deal with stability and vibration problems. Here it is shown how these problems can be advantageously handled by using Rayleigh's approximate method. At the end, Prof. Southwell raises the controversial question of priority connected with the Rayleigh-Ritz method. Without doubt, the fundamental idea of this method belongs to Rayleigh, but the part of Ritz should not be minimized, since he added much in its development. Rayleigh used the method only for an approximate calculation of frequency of the gravest mode of vibration of complicated systems, and was doubtful (see Rayleigh's papers in *Phil. Mag.*, 47, 566; 1899: 22, 225; 1911) regarding its application to the investigation of higher modes of vibration. Ritz generalized the method and made of it a powerful tool for solving problems of engineering and mathematical physics.

It is the belief of the reviewer that in this book, Prof. Southwell has made a very valuable contribution to the literature of the engineering sciences. It can be recommended both to students who wish to pursue advanced studies in the field of elasticity and also to engineers interested in application of the theory of elasticity to problems of machine and structural design. Throughout the book one finds a clear presentation of the subject given by a man who himself has contributed to its development. The book contains many interesting problems which give the student an opportunity to try his own skill and thus to improve his knowledge by exercise. S. TIMOSHENKO.

Insulin

Insulin:
its Production, Purification and Physiological Action. By Douglas W. Hill and Dr. Frederick O. Howitt. Pp. xi+219+4 plates. (London: Hutchinson's Scientific and Technical Publications, 1936.) 12*s*. 6*d*. net.

IN the fascinating history of the gradual unfolding—it is too early yet to say elucidation—of the function carried out by the pancreas by means of its internal secretion, insulin, one is above all impressed by the ingenuity of the physiological experiments, which, in the early days, at all events, rather overshadowed the chemical work.

When the authors of this monograph set themselves the task of sifting the evidence that has accumulated since the first preparation of insulin, it was indeed a difficult one. "Very little systematic work under well-defined and what may be called standard conditions has been recorded. Hence it is difficult to place a fair estimate on the value of the results from each set of experiments". They make this observation concerning the action of insulin, but, with some notable exceptions, the criticism is true of much of the work on this hormone. Among the exceptions, the authors might have given greater prominence to the outstanding work of Abel, Freudenberg, Scott and their collaborators.

The book attains a highly valuable object in that it is provocative of further research. Whether it be some important question of principle or theory, or some smaller point of observation of fact, it is certain that it must stimulate the seeker after truth to find the answer to many problems left unsolved. Time and again the authors show how contradictory are the results that have been published: one set of workers forming one conclusion, whilst the evidence of another group leads to the reverse. The reason for the diversities of opinion is nearly always to be found in one or both of two causes: either too little allowance has been made for animal variations (for example, one rabbit serving as control for another), or, effects ascribed to insulin have, in reality, been obtained with samples of such impurity that they would be more correctly described as protein mixtures containing some insulin. It is frequent in the literature to find no reference made either to the method of test or to the potency of the sample used, which makes it quite impossible to assess the value of conclusions.

Before the chapters on the chemical, physical and physiological properties of insulin, the authors wisely direct attention to the relative impurity of much of the material used, which, as they suggest, may yet furnish records of some value. It is difficult to see, however, how any value could be attached to observations on the solubility of 'insulin' of potency 40 units/gm., that is, containing 99·8 per cent of impurity. Even in 1923, when these observations were published, much purer material was available.

Of particular interest is the chapter that deals with the effect of the other hormones upon insulin action, and it is a tribute to the authors that one should be led to speculate beyond the subject that they set themselves to treat, stimulated to inquire further into the question of endocrine balance.

The section on standardisation calls for some criticism. The emphasis laid on such questions as the distribution of sugar between plasma and corpuscles, which has little bearing on standardisation, in which whole blood is always laked, is an extravagant use of valuable space when some interesting aspects of testing could not even be touched on. In a work of which the stated object is to sift the evidence, it is surprising to find quoted an observation made in 1923 to the effect that at least three rabbits should be used for a test, whilst no mention is made that for years now about five tests on twenty rabbits each would be considered a reasonable number for an accurate assay. The suggestion of the greater regularity of behaviour of mice is not in accord with the general consensus of opinion to-day. The observation of Marks, that the mouse test gives results 15–30 per cent higher than the rabbit test, was made with crystalline or highly active amorphous insulin using a standard of much lower activity: it has been shown that the discrepancy may be in the opposite direction when relatively inactive substances are assayed.

The book is attractively presented, and the subject matter most clearly arranged. Above all, the bibliographies at the end of every chapter will be of inestimable value.

K. C. L.

A Book of Fishes

Naturgeschichte und wirtschaftliche Bedeutung der Seefische Nordeuropas
Von Prof. Dr. Ernst Ehrenbaum. (Sonderausgabe aus dem Handbuch der Seefischerei Nordeuropas, Band 2.) Pp. x+337+26 plates. (Stuttgart: E. Schweizerbart'sche Verlagsbuchhandlung (Erwin Nägele) G.m.b.H., 1936.) 44 gold marks.

DR. ERNST EHRENBAUM, formerly of Heligoland, afterwards director of the Fisheries Institute in Hamburg, has been for many years one of the best known and most trusted of all the many naturalists engaged in fishery investigation. Dr. H. Lübbert, once better known as Captain Lübbert, is a rare blend of seaman and scientific man; he has had more to do than any other man with the development of the German sea-fisheries, and he has been called in to advise Governments in many parts of the world. Thirty years ago, Captain Lübbert founded *Die Fischerbote*, one of the very best of all fishery journals; and for most of the time since then the two have edited it together. Now they have embarked on the great enterprise of publishing a "Handbuch der Seefischerei", of which a good many parts are now ready, and which will form at last an encyclopædia of all our northern fisheries—from the Murman Coast to Brittany, from oysters to whales. Nearly two hundred years ago Duhamel du Monceau did much the same thing, and did it wonderfully well; another hundred years and we come to Isaac Walton and Cotton's "Universal Angler"—little, but good; yet another fifteen hundred years and we make the best we can of Oppian.

The first volume of the great "Handbook" contains, or will contain, a sketch of oceanography, a description of the sea-bottom, an account of marine vegetation, a discussion of the diet and ultimate sources of nutrition of marine animals, and in general of the balance of Nature in the sea. The book before us is the second volume, and deals systematically with the fish of our northern seas; it gives a full but very concise account, in some 300 closely printed and richly illustrated pages, of all our marine fishes; and not only the salmon but also most of our fresh-water fishes come into the story also, as inhabitants of the Baltic Sea. Almost every fish has its figure, except a very few which are obviously not needed here: such as some of the rarer deep-sea *Macruri*, or some of the Mediterranean and Atlantic fishes, *Box*, *Sparus*, *Pagellus* and the like, which only come to our northern seas as errant stragglers. Few of the figures are original; they are mostly drawn, and admirably reproduced, from Smitt, Collett, Joubin, Day, and occasionally Cuvier.

This is a book not only about fish but also about fisheries; for ours is a commercial age, and we want to know the fish in the market as well as the fish in the sea. Day's "British Fishes", written fifty years ago, and for most purposes our standby still, is an excellent book, full of information and knowledge. But the fisheries of the world have changed mightily in the half-century from Day to Ehrenbaum. When Day wrote, the saithe (for example) was caught "by angling, or line-fishing, the lugworm being found a good bait"; it was "not much sought after, being held in little esteem". But now, as Ehrenbaum tells us, 100,000 tons (114 million kilos) were brought to market in 1932 from our northern seas, all the way from the North Sea to Iceland and Spitsbergen. Fifty years ago, the megrim was a rare fish, to be recorded one by one; to-day at least 6,000 tons come to market every year, and it fetches a good price, in Germany even a high one.

The catch and the value of each and all of the marketable fishes are dealt with briefly but adequately in this book, but so indeed is every other part of the subject; Dr. Ehrenbaum omits little, and forgets nothing. The few pages on the cod tell how G. O. Sars studied its development, how Michael Graham and others have studied its rate of growth, what Hjort has written on its migrations, how Einar Lea has studied its scales. An excellent account of the mackerel tells of its migrations between the deep sea and the coastal waters, how its diet changes with place and season, and how it fasts about Christmas or New Year; how we catch it, on one hand by line and on the other by the trawl; and how, unlike the salmon or the sprat, it seems to spawn at one and the same time, whether off the Irish coast or at Heligoland. The part on the tunnies, tunny, bonito, germon, pelamyd, albacore and so on, in all their puzzling and shifting nomenclature, is particularly good. There is an up-to-date account, based mostly on R. S. Clark's work, of the many northern skates or rays and their eggs; Holt's work on the gobies, Tate

Regan's amazing account of the males of *Ceratias*, the work of C. J. G. Petersen and many others on the varying rate of growth of plaice according to the density of population and the available food, and of course Johannes Schmidt's epoch-making studies of the eel—all these are among the many matters clearly and lucidly explained.

In short, this is a good book and a useful one all through. It is not for easy reading but for reference and study; and few will open it without finding what they want to know. D. W. T.

The New Agriculture and World Peace

Nations can live at Home
By Dr. O. W. Willcox. Pp. 279. (London: George Allen and Unwin, Ltd., 1935.) 10*s*. net.

PEACE is the paramount need of the world to-day. Of the many factors, complex, obscure and profound, which tend to endanger peace and produce war, one at least can be definitely diagnosed as the increasing pressure of population, in some parts of the world, on land resources. Any practical means that can be applied to reduce that pressure should, if coupled with the requisite social and political adjustments, become a powerful agent of world peace. Such is the message of this book, a message of profound and vital importance, of particular interest to scientific agriculturists and students of population problems, but also of wide general appeal. Many nations are at present quite unable to obtain from their own soil all their requirements in food and raw material, which they must import accordingly and pay for by exports. But with the vast shrinkage in international trade and the increasing difficulties of keen and world-wide competition, this method of obtaining the desired supplies may appear, to some of the nations so situated, as much more difficult and less satisfactory than that of actual, and if need be aggressively, warlike attempts to find additional territory outside their own boundaries. Dr. Willcox, however, now offers to the peoples in these straitened and parlous circumstances a simpler, easier and much more effective method: that of greatly increasing the yields of their own soil, by using to their fullest extent the wonderful powers of crop productiveness that modern plant-breeding and soil science—the new agriculture or agrobiology—has placed within their reach.

The book makes a powerful and compelling twofold appeal: first, because of the inherent interest of the wonderful results claimed on behalf of agrobiology in respect to vastly increased yields from the land; and secondly, the profound economic, social and political consequences of such agrobiological advance.

Whilst fully admitting, however, that plant-breeding or genetics and soil science have made immense strides and produced results of the kind and magnitude herein described, backed up indeed by large-scale field work in many parts of the world, it nevertheless seems to the present reviewer that the difficulties due to such things as plant pests, drought, flood and other meteorological disturbance, the human element, and above all costs, have just possibly been brushed aside a little too indifferently.

It was perhaps scarcely possible, within a book of this compass, to deal fully with all the practical difficulties in technique. The far greater difficulty is that of getting the new methods generally adopted by those very conservative and sceptical people, the farmers. In the very interesting chapter dealing with the special conditions in various 'deficit' or 'beyond the threshold' countries—Great Britain, Germany, Italy, Japan—Dr. Willcox describes the remarkable results obtained by the Better Farming Association in Japan, in the matter of rice yields. The best type of farmer, using the best and most productive variety of rice plant, under the best agrobiologic conditions, obtained yields several hundred per cent above the average. But it was very difficult, if not impossible, to arouse the interest of the majority of farmers in Japan.

There is, of course, the further complication of over-production in those parts of the world which are mainly agricultural, and supply world markets. This is touched upon in the present book, and provided for plausibly if not too convincingly.

Some of the figures given for crop yields or possibilities are startling enough, especially when combined with reduced crop cycles so that several crops can be taken from the unit of land each year. These are studied at some length in relation to population density, and the relative values of different crops from the protein–carbohydrate ratio point of view. It is generally concluded that population densities up to 15,000 or more per square mile are not beyond the bounds of agrobiological possibility; but it is scarcely fair to the author to state these bald figures without the accompanying well-reasoned arguments in support.

W. G. L. C.

Libraries for Scientific Research in Europe and America

By H. Philip Spratt. Pp. 227. (London: Grafton and Co., 1936.) 10*s.* 6*d.* net.

THIS informative little book is the result of a series of tours made by the author in Europe and North America, and sets out to describe the research facilities existing in the more important specialist libraries of the two continents—not only from the point of view of the librarian who wants to know the latest methods in actual use, but also from that of the research worker anxious to learn in what way modern libraries administer to his needs in the search for published information on his subject.

After describing six representative libraries in London, the author takes us *via* Paris and Brussels to Scandinavia, Germany, Poland, and Russia—finding in the latter country that most of the libraries are dominated by "books on science (and communism)"—and thence to America, to which about one half of the book is devoted. In the case of each library—and nearly a hundred are included in the book—Mr. Spratt gives details of the arrangement of catalogues and indexes, of the classification used (with a distinct leaning towards the Universal Decimal Classification), of information services and the provision of photographic and other apparatus, and of the general administration in so far as this interests the public as users.

The survey is thorough and there is evidence throughout of the author's practical knowledge of the problems involved and of his first-hand inquiry into the present methods of dealing with them. The index is well constructed but lacks balance. The entry "British Museum, 47" supplies the information that the Bibliothèque Nationale ranks with the British Museum, while "John Crerar Library, 186" refers the reader to a five-page description of that institution.

A. G.

Primitive Law

By A. S. Diamond. Pp. x+451. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1935.) 25*s.* net.

MR. DIAMOND holds that Sir Henry Maine's conception of primitive law as inseparable from the concepts of primitive religion and morality is no longer tenable in the light of modern research, and, further, that in the development of early law there is a parallelism which corresponds with economic and social progress. Thus the code of Hammurabi, for example, is formulated in a society which corresponds in economic development with the societies which produced the codes of medieval Europe. The undoubted religious elements which appear in the codes as they have come down to us are due, he holds, not to the fact that they embody survivals from an earlier stage in which religious belief, law and morality were undifferentiated, but are due to introductions by priestly scribes at a date later than the formulation of the codes.

Mr. Diamond has made a careful analysis of such early codes as have survived, and has surveyed in detail the practice of modern primitive peoples for evidence in support of his view. This vast mass of fact brings out clearly certain weaknesses in the over-simplification inherent in Maine's point of view and method. On the other hand, as regards Mr. Diamond's principal contention, however much may be conceded to priestly intervention, the distinction by which the author would seek to rule out Maine's view is largely a question of definition and determination of the point at which what he regards as law begins.

The Extra Pharmacopœia of Martindale and Westcott

(Published by direction of the Council of the Pharmaceutical Society of Great Britain.) Twentieth edition. Vol. 2. Pp. xxxvi+889. (London: The Pharmaceutical Press; H. K. Lewis and Co., Ltd., 1935.) 22*s.* 6*d.* net.

W. H. MARTINDALE, who had for many years carried on his father's work as author of the "Extra Pharmacopœia", died in 1933. He had brought out a new edition every four years and the book has become indispensable. He produced the first volume of the twentieth edition in 1932. The second volume has now been prepared by a committee of the Pharmaceutical Society—under the editorship of Mr. C. E. Corfield, the editor of the "British Pharmaceutical Codex". This committee has undertaken the heavy task of preparing future editions. It has always been a source of wonder that Dr. Martindale should be able to do all this by himself; Dr. Westcott's collaboration only lasted for a period.

The first volume deals with the manufacture, composition and uses of drugs. The second volume consists of a series of appendixes dealing with diverse subjects such as the analysis of bread and butter, health resorts, disinfectants and proprietary medicines. The committee has managed to carry out a thorough revision without destroying the book's individuality. Most of the familiar sections are still there, expanded slightly and brought up to date. The section on modern views of atomic structure now occupies six pages. Modern methods of biological assay have been included, and there is much interesting information about recent work on hormones and vitamins.

Mechanics and Hydrostatics

By Dr. R. G. Mitton. (Dent's Modern Science Series.) Pp. ix+275. (London: J. M. Dent and Sons, Ltd., 1936.) 3*s.*

THIS volume has been designed to cover the School Certificate and Matriculation courses in mechanics and hydrostatics. The author has presented the subject matter in a very lucid and interesting manner, and a noteworthy feature is the number of excellent photographic reproductions illustrating the practical applications in industry of the principles discussed. It will also be encouraging to up-to-date teachers to find that the author has adopted the policy of treating absolute units as fundamental from the earliest stages.

The book is amply supplied with exercises, many of which have been taken from the various School Certificate and Matriculation examination papers. Answers to these are also given.

Seasonal Changes in the Underwaters of Bermuda

By Prof. Walter Garstang

AFTER a visit last year to the Bermuda Biological Station, I directed attention in a semi-popular article to the unique opportunities at this lonely Atlantic island for oceanographic research, and suggested that continuous local investigation of the deep water around the island would be likely to hasten a solution of the "Atlantic Water" problem, which has such important bearings on European fishery and other questions (*Discovery*, December 1935). This opinion has been considerably strengthened by the subsequent study of various hydrographic reports, and especially by a collation of the published data recorded by various research vessels in the immediate neighbourhood of the island.

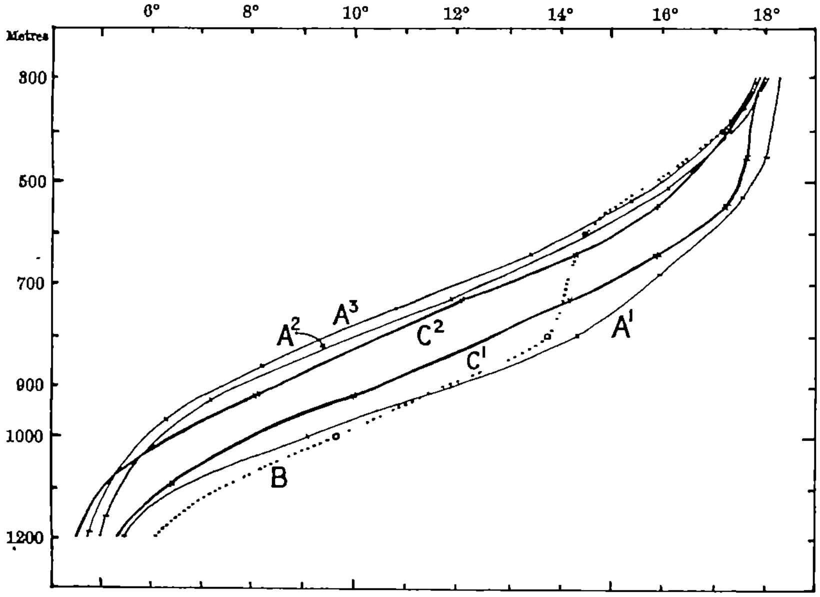

FIG. 1. Temperature curves of selected Bermuda stations (intermediate layer only). A^1, A^2, A^3: *Atlantis*, February, April and December 1932, respectively. B: *Bache*, February 1914. C^1, C^2: *Challenger*, April and May 1873, respectively.

Temperature and salinity determinations at the following stations have been used: H.M.S. *Challenger* (temperatures only), stations 37 (April 24, 1873) and 57 (May 30, 1873); st. 10179 of the U.S. Fish Commission's vessel *Bache* (Feb. 18, 1914); st. 1339 of the Danish *Dana* Expedition (May 10, 1922); and six stations of the Woods Hole Oceanographic Institution's vessel *Atlantis*, namely, 1125 (Dec. 5, 1931), 1145 (Feb. 17, 1932), 1220 (April 17, 1932), 1359 (Aug. 27, 1932), 1431 (Dec. 5, 1932), and 1464 (Feb. 12, 1933). These stations are dotted about the island in various directions, all within a radius of sixty miles, except the first *Atlantis* station (1125), which lay 120 miles to the north-west. The data for this station furnish one of the extremes in the range of variation, but its inclusion seems to be amply warranted by a comparison with other stations at the same period.

The general characteristics of the water-column in the Sargasso Sea are well-known, and many temperature curves from the region have been figured by the *Challenger*, *Dana* and other expeditions. All show beneath the variable surface region two more or less vertical portions, representing relatively uniform layers: (*a*) a sub-surface layer of high salinity (*c*. 36·5 per mille) below the influence of solar radiation (150–400 metres), but preserving the effects of winter convection at a nearly constant temperature of 17°–18° (the average surface minimum), and (*b*) the deep waters (below 1,000 metres) of low salinity (less than 35·0 per mille) and temperature less than 5°. Between these two strata lies an intermediate layer (*c*. 400–1,000 metres) the variations in which are the main subject of this communication. It ranges over a considerable series of closely stratified temperatures and salinities, which confer a characteristic slope upon this portion of the curve. When the curves of the various Bermuda stations are superimposed upon the same large sheet of graph paper, it can be seen that the slope representing the intermediate layer changes its position with the season of the year, running at a higher level and to the left (that is, nearer the surface and through lower temperatures) during the summer and autumn, and lower down to the right (that is, through higher temperatures) during the winter and early spring—the very opposite of seasonal changes at the surface. Temperature and salinity curves follow the same orderly cycle, which, so far as the records go, differs only in amplitude from one year to another

(Fig. 1). The *Bache* curve for February is unique in showing autumn conditions above and winter conditions below. The soundings must have been taken while the winter change was in progress.

In the available space only a few of the curves can be conveniently reproduced, but the regularity of the sequence and the varying amplitude of the annual change come out almost equally well if we take a few representative isotherms and isohalines from the curves, and plot their levels in the water-column at the various times of the year represented. The invaluable *Atlantis* data naturally furnish the basis of such a diagram (Fig. 2). The continuous lines represent the varying depth of the isotherms 17°, 15°, 11·5°, 8° and 6° and between the first four of these the isohalines 36·2, 35·6 and 35·2 per mille run as lines of dots and dashes. The *Challenger* records in 1873 for April (C^1) and May (C^2) have been connected with those of the first *Atlantis* February, the *Dana's* for May 1922 with the *Atlantis* April, and the *Bache's* for February 1914 with the second *Atlantis* December—of course, merely for convenience of reading.

It is plain from the figure that the active parts of the annual cycle are concentrated in the period from December to April or May. In February there is a sharp drop in the level of the isotherms (and isohalines) by some 100–300 metres, and in April (or April and May) a corresponding, but not necessarily an equivalent, rise. It should be borne in mind that, owing to the normal graduation of temperature and salinity from above downwards, the lowering of an isotherm implies a deepening of the mass of warmer water above it, and the lowering of a whole series of isotherms a general increase of temperature throughout the water-column represented. Similarly, a raising of the isotherms implies an upward extension of the colder waters and a corresponding decrease of temperature at the depths under consideration; so also with isohalines and salinity, *mutatis mutandis*. From April to December, the *Atlantis* isotherms and isohalines show little or no changes of level, though there is a slight upward tendency, especially of the isohalines. It may therefore be inferred that the relatively low levels of the *Challenger* isotherms in May 1873 and the high levels of the *Dana* isotherms in May 1922 were probably maintained throughout the summer of their respective years, implying relatively high temperatures throughout the intermediate layer in the summer of 1873, and low temperatures in 1922. The conditions in 1932 were intermediate, but nearer those of 1873 than of 1922, though attained earlier, in April instead of May. Confirmation of the exceptional warmth of the intermediate waters throughout the Sargasso Sea in the summer of 1873 has in fact already been given by Helland Hansen when comparing the *Challenger* station 65 (halfway between Bermuda and the Azores) with corresponding stations of the *Michael Sars* in June 1910 (Murray and Hjort, 1912, Fig. 210).

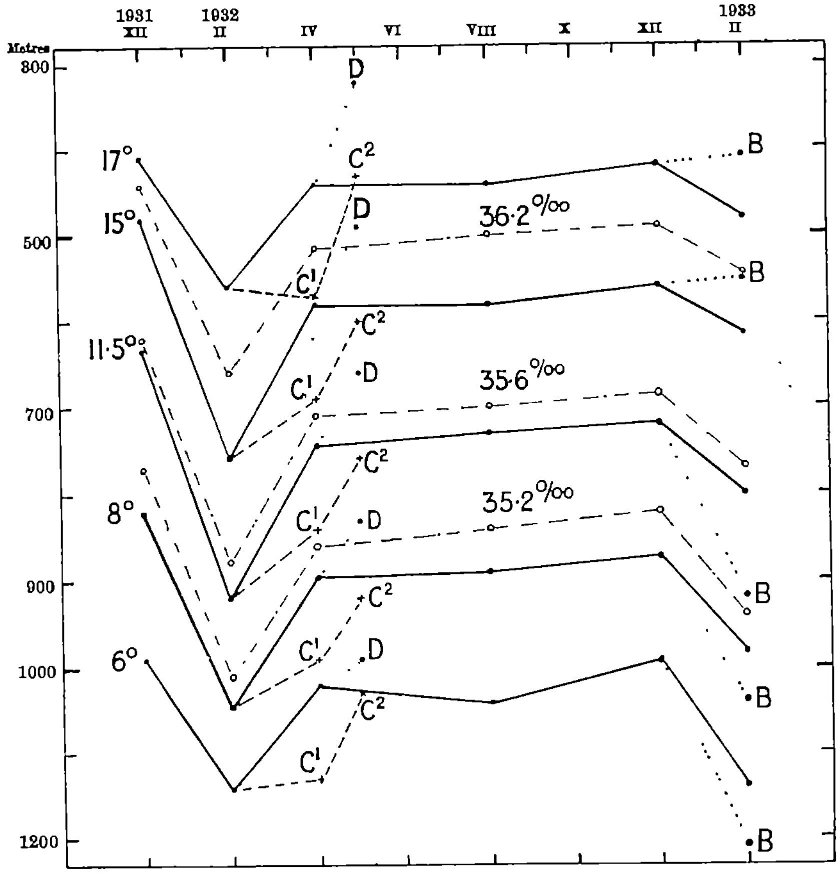

FIG. 2. Depth of selected isotherms and isohalines from the complete curves, showing monthly changes.
●—, *Atlantis* isotherms.
○—·—, *Atlantis* isohalines.
×— —, *Challenger* isotherms (C^1, April; C^2, May 1873).
● . . . , *Dana* (*D*) and *Bache* (*B*) isotherms.

So far, I have described this sequence in terms of obvious changes in the level of isotherms and isohalines, which, as oceanographers know, are liable to disturbance from a variety of causes. Although some of these factors could at once be eliminated from the present case, it is sufficient here to note that the Bermuda cycle is not conditioned simply by a periodic undulation of the isotherms, but by measurable changes in the temperature-salinity ratio. Fig. 3 shows the salient differences in the salinity associated with various degrees of temperature at the Bermuda stations regardless of depth. The ratio of salinity to temperature attained a maximum height in December 1931, and was followed in February by a smart fall, which continued to April. The *Dana's* records for May 1922 show the minimum for the whole series, thus pointing to the probability that a fall in the salinity ratio is a regular phenomenon from February until April or May. After April 1932, the ratio rose slightly through the summer and autumn to December, when it was succeeded by a marked rise in the following February, greater for the lower degrees of temperature than the higher.

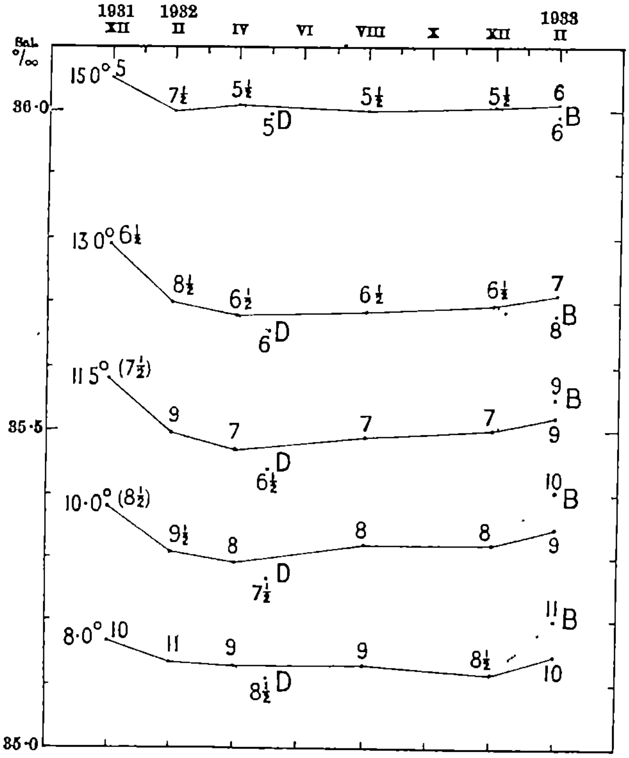

FIG. 3. Salinity ratios for selected degrees of temperature (from *T/S* curves). The numerals represent approximate depths in hektometres. *Atlantis* data with addition of *Dana* (May) and *Bache* (February).

The apparent inference to be drawn from these changes is that occasionally in February (1932), and regularly in April or May, there takes place a general infiltration of alien water of less than normal salinity, the influx of which declines during the summer and autumn and is usually cut off more or less completely in February (1914, 1933). This cycle is, of course, precisely that of ice-bound coastal waters, locked up by frost in winter, and released in full flood in spring. The only possible source of such water in the present case is the coastal tract of mixed waters on the north side of the Gulf Stream, mainly derived, according to Bigelow, from the Gulf of St. Lawrence by the Cabot Strait, but mixed undoubtedly with Gulf Stream overflows and the coastal waters of the Gulf of Maine, probably also in severely 'Arctic' years like 1929 with contributions from the Labrador Current itself.

This conclusion may seem to conflict with some recent opinions as to the nature and relations of the Gulf Stream, but, so far as I can see, it is not opposed by any established facts. If we turn to Jacobsen's hydrodynamic current-charts (1929, figs. 53–56) we find the hub of the Atlantic circulation placed off Cape Hatteras in lat. 36° N., long. 74° W., where Gulf Stream and Antillean Current turn markedly east and give rise to great eddies on the right, some of which are completed as inner, middle and outer anticyclonic circuits, the middle one bathing Bermuda on its way to the Windward Isles to a depth of some 500 metres. As the depth of reference is only 1,000 metres and the deep waters, admittedly recruited from the "cold wall", are certainly moving in spring, these charts cannot be regarded as defining the bottom limit of the currents indicated. The *Challenger*, in fact, at st. 37 in April found a south-east undercurrent at Bermuda from 200 fathoms down to 400 fathoms (350–750 metres) moving at a rate of about ¼ mile per hour above and 1/10 mile below. Such a current would require at least two months to bring water to Bermuda from the water-parting off Cape Hatteras, but it may well have been twice or three times as strong during the climax of the May flood.

It is also noteworthy that exactly abreast of Jacobsen's water-parting (vortex ?), but on the landward side of the Gulf Stream, lay the *Bache* station 158 and the *Dana* station 1349 (the former in lat. 36° 12′, long. 74° 25′, the latter in lat. 36° 16′, long. 74° 33′), which presumably reveal the relations of the coastal waters to the Gulf Stream in February and May respectively. In February, Bigelow found an isolated 'tongue' of water of temperature 11°–12° and salinity less than 35·2 per mille dipping down from the surface like a 'waterfall' over the edge of the continental shelf to a depth of some 300 metres, and separated from the Gulf Stream by a nearly vertical wall of water 500 metres deep, of 35·5–36·0 per mille salinity. In May the *Dana* found this wall, from

200 metres downwards, bent outwards as an inclined plane, beneath which the mass of coastal water, *colder and less saline throughout than in February* 1914, was completely continuous (except the most superficial stratum less than 35·0 per mille) with the intermediate layers of the Gulf Stream column. At 300 metres the temperature and salinity at the *Bache* station were 11·4° and 35·19 per mille; at the *Dana* station in May they were down to 8·17° and 35·08 per mille. At the *Dana* station 1351, in the Gulf Stream itself, water with approximately this temperature and salinity lay 600 metres deep. At Bermuda at the same time it lay at 900 metres.

There can indeed be little doubt, after comparing these facts and the illuminating sections* provided in their respective reports by Bigelow (1915, figs. 11, 12, and 49), Nielsen (1925, Section 4), and Jacobsen (1929, fig. 11), that during the flood period in spring the pent-up coastal waters are incessantly mixing with the left side of the Gulf Stream, to pass through it in part, and for the rest to be swirled eastwards into the general circulation of the Sargasso Sea (cf. Jacobsen, p. 19). Iselin also, in a preliminary forecast of *Atlantis* results, has remarked of the Gulf Stream: "Very little of the Gulf water remains when Cape Hatteras is reached. The current is of course continuous, but gradually the Gulf of Mexico water becomes replaced at all depths by Sargasso Sea water *or a mixture of this and Slope Water*" (1933, p. 231).

Altogether, in spite of the fragmentary data on which it necessarily rests at present, the case for a seasonal cycle in the Sargasso Sea and its dependence on the periodic release of ice-bound coastal water seems unmistakable. The interest of the relation is practical as well as theoretical, for it opens up at once the prospect of our ability to attack the 'Atlantic Water' problem from a new and much more promising angle. The periodic incorporation into the intermediate layer of the Sargasso Sea of millions of tons of alien water must result in a periodic eastward spreading of the whole water mass. Annual variations in the amplitude of the extension may well be concerned in determining the irregularities of Atlantic incursions upon the coasts of Europe. If this argument is sound, the first step should obviously be to confirm the periodicity at Bermuda by regular observations at much more frequent intervals, especially from December to May, so as to date the changes with greater precision, and over a period of years sufficient to include the greater annual fluctuations. Only at Bermuda is such a continuous record practicable. Unfortunately, we have missed the opportunity of recordthe effects on the Sargasso Sea of the great frost and floods of the last American winter.

In conclusion, my thanks are gratefully tendered to Dr. E. J. Allen, of Plymouth, Mr. Donald Matthews, of the Admiralty, Dr. J. N. Carruthers, of Lowestoft, and Mr. A. J. Clowes, of the *Discovery* Expedition, for help in getting access to relevant literature.

---

* A temperature section from *Atlantis* data given by Iselin (1933, fig. 2) for the same region in February cannot readily be compared owing to lack of isohalines. It is noteworthy, however, that the isotherms are shown appreciably lower than in the *Dana*'s sections for May, though with less difference than at Bermuda.

The 'Specific Action' of Ultra-short Wireless Waves

By Prof. W. E. Curtis, F.R.S., Dr. F. Dickens, and S. F. Evans

DURING the last ten years or so many investigations have been made concerning the biological and medical effects of short wave radiation. The absorption of such radiation by tissues necessarily results in the liberation of heat, and many of the effects observed are admittedly due to this cause. They could alternatively be produced by other methods of heating, although the radiation method frequently offers special advantages and potentialities. It is being pursued energetically in various laboratories and clinics, and appears to rest on a sound theoretical and experimental basis[1].

The literature of the subject, however, contains frequent references to other effects, usually termed 'specific', in the sense that they can only be produced by the short-wave method, that is to say, that they are not primarily thermal in origin. In some cases also it is claimed that the effects are restricted to certain wave-lengths, or that an optimum wave-length exists. So far as is known at present, from physical and chemical evidence, radiation of these wave-lengths (3–15 metres) is not directly convertible into atomic or molecular energy, and such observations, if substantiated, would be of great interest and importance. We have therefore thought it desirable to scrutinise the evidence rather carefully, tracing the various references to their sources, and attempting, where possible, to repeat the experiments in question.

The effects claimed are diverse in character, including metabolic changes in tissues, physical changes in liquids and colloids, decolorisation of dyestuffs, bactericidal action and so forth. The one feature common to them all, we find, is the absence of any incontrovertible proof of their existence, and this in spite of their unquestioned acceptance by numerous authors of reviews and research publications. The details which follow should serve to expose the very unsatisfactory situation which exists at present, and perhaps to stimulate further investigation of the alleged phenomena.

(1) As an instance of effects which are probably due to the inadequacy of the precautions against heating, we may take the results of Reiter[2], who claimed to have established the existence of an immediate destructive action on the metabolism of malignant tissue when exposed to radiation of wave-length 3·4 metres. In attempting to repeat these observations*, we found that to maintain approximate constancy of temperature it was necessary to take much more drastic measures than Reiter appears to have done. For example, in order to keep the tissue contained in a suitable vessel, at 40° C., it had to be immersed in a bath containing liquid paraffin at 6° C. Under these conditions, no effect on metabolism was observed[3] when the specimen was subjected to intense irradiation on a wave-length of 3·4 m.

(2) The importance of surface tension effects has been stressed by Schliephake and Compère[4], who claim to have observed a lowering of surface tension in certain colloidal solutions including blood and serum. They consider that although earlier observations might conceivably be explicable as heat actions, "it is already permissible to say that we have now obtained for the first time certain proof of the existence of an effect of ultra-short waves that cannot be explained by the action of heat alone". The experiments referred to were made by allowing serum and other liquids to run from a stalagmometer placed between the electrodes of a 6-metre transmitter, surface tension being measured in the usual way by counting the number of drops for a given volume. It is stated without supporting data that "even a rise of temperature of several degrees had no influence whatever on the drop formation", and also that any possibility of a heat effect was rigorously excluded by comparative experiments in which the drops were warmed by radiant heat. No details of field strength or of the concentrations of the reagents used are given, although Schliephake in his book[5] (p. 52) states that definite dilutions are necessary. We have attempted to repeat this work, but without success. The stalagmometric method of measurement of surface tension was found to be entirely unsuitable for this purpose, since the heating effect was very great and the temperature of the drops could not be measured with precision. Using the more accurate and convenient torsion balance method, which further allows the determination of the temperature of the mass of liquid, we were unable to find any effect whatever on the surface tension of serum, although an effect of the magnitude reported by Schliephake would have been readily detected. The field used was of such strength that in stalagmometer experiments the drops of serum were heated through about 5° C. in 10 seconds. The variation of surface tension in the short wave field has been referred to in the literature as the "Schliephake Effect" but, in our opinion, proof of its existence is entirely lacking.

(3) Some further examples of specific action are given by Schliephake in his book. Working with Recknagel, he claims to have observed changes in the viscosity and stability of colloids which are opposite to those caused by rise of temperature. Only sixteen lines of description of these fundamental phenomena are given, and in reply to a request for fuller information it was learned that this could not be given "on personal grounds".

(4) Of particular therapeutic interest are the claims put forward in respect of bacteriological effects. Haase and Schliephake[7] claim that they have demonstrated killing of staphylococci and tubercle bacilli by exposure at body temperature to short wave radiation; Recknagel and Schliephake[8] report a marked reduction of the activity of diphtheria antitoxin following similar treatment, and attention is directed to the confirmatory work done by Szymanowski and Hicks[9]. In a paper[9] published six months later, however, Szymanowski and Hicks withdraw their earlier results on toxin and also report that, repeating the work of Schliephake and Haase on staphylococci, they were unable to establish any effect of the high-frequency field. They conclude that "the consistently negative results reported in this paper lend further evidence to the belief that the only direct therapeutic action of ultra-high frequency radiation is related to the problems of conductivity in tissues and consists in an elevation of temperature". In his book Schliephake does not refer to the latter paper.

---

* On behalf of the British Empire Cancer Campaign.

(5) A book on "The Foundations of Short-Wave Therapy" by Holzer and Weissenberg[10] has recently appeared. These authors are vague in their references to 'specific actions', but refer to colour reactions, notably decolorisation of the dye pinacyanol in a short-wave field[11]. As this appeared to be a simple and striking example of the effect of short waves, we attempted to repeat it in our laboratory, but without success, and we are informed in a personal communication from Dr. Holzer that he has since been unable to reproduce the effect.

(6) Another similar example which we unsuccessfully attempted to verify is Esau's observation, quoted by Pflomm[12], that turpentine oil could be hardened by exposure to a short-wave field ; no details were available, and although we have asked Prof. Esau for fuller information we have as yet received no reply. Still more mysterious are the effects on operators of short wave appliances reported by both Holzer and Schliephake. The precise nature of these effects appears somewhat indefinite, but their principal manifestations are psychological and can be prevented by suitably screening the apparatus. The present writers, working on 3 metres with totally unscreened apparatus using a power much greater than that quoted by Schliephake, have failed to notice any effects following daily exposure, and they have been informed by research engineers working with very high power on ultra-short wave-lengths that such effects are unknown in their experience.

(7) One of the most promising lines of attack would appear to be the investigation of anomalies in dielectric constants at these frequencies, with a view to possible correlation with dipole moment phenomena. Hausser[13] has published work in which such effects were observed for sphingomyelin at a frequency corresponding to a wave-length of 5 metres. This example, if confirmed, would constitute the nearest approach to the clear demonstration of a specific effect yet made ; it is therefore of particular interest, though it appears from personal communication with the author that the position is not yet cleared up to her entire satisfaction. In any case its relationship, if any, to the spectacular effects claimed by the more enthusiastic protagonists of specific short-wave actions is still obscure.

We believe that, with the exception of the last example, the above selection of experiments and observations is typical of those upon which the hypothesis of a specific action has been built. If such an effect exists, it should be possible for the discoverers to describe at least one clear-cut experiment which could be repeated by other workers. In the absence of such evidence we consider that the great mass of inconclusive observations which has been presented is a very insecure foundation for the rapidly growing belief in specific short-wave therapy. Whilst the possible existence of specific actions of ultra-short waves cannot be denied, in our opinion such effects have not as yet been adequately demonstrated. We therefore find ourselves in agreement with the conclusions of a recent report to the Council on Physical Therapy of the American Medical Association, by Mortimer and Osborne[14] :

"There is no conclusive evidence from the literature nor were we able to substantiate the claim of specific biologic action of high frequency currents (short-wave diathermy). In our opinion the burden of proof still lies on those who claim any biologic action of these currents other than heat."

Obituary

Prof. W. E. Dalby, F.R.S.

PROF. WILLIAM ERNEST DALBY, emeritus professor of engineering in the University of London, who died at his home at Ealing on June 25 at the age of seventy-two years, received his practical training in engineering in the Stratford locomotive works of the Great Eastern Railway, and afterwards at the L. and N.W.R. works at Crewe. His duties at Crewe afforded him exceptional facilities for gaining experience in all branches of engineering work, and in construction and maintenance of both permanent way and locomotive. In 1894 he was at the University of Cambridge as assistant to the late Sir Alfred Ewing, who was then developing a Department of Engineering in that University. He left Cambridge to become professor of mechanical engineering and applied mathematics at the Finsbury Technical College, and in 1904 he succeeded the late Prof. W. C. Unwin as University professor of engineering at the Central Technical College, South Kensington. When that College was incorporated in the Imperial College of Science and Technology as the City and

Guilds (Engineering) College in 1907, he was made a member of its governing body and remained so until his retirement from the professorship in 1931. He was Dean of the City and Guilds College from 1906 until his retirement, and at the jubilee celebrations of the College in 1934 he was elected honorary fellow of the City and Guilds of London Institute.

Prof. Dalby served as dean of the Faculty of Engineering in the University of London for four years and as senator for eight years. He was elected a fellow of the Royal Society in 1913, was for some years vice-president of the Institution of Mechanical Engineers, and at the time of his death was a vice-president of the Institution of Civil Engineers. The Institution of Naval Architects also elected him honorary vice-president. He was president of Section G (Engineering) of the British Association in 1910, and was a member of some of that Association's research committees, notably the Gaseous Explosions Committee. During the Great War, Prof. Dalby served on several Government committees, and carried out much confidential research work for all three of the fighting Services. Of the many committees on which he served during the War and afterwards, mention may be made of the Board of Invention and Research, the Engineering Section of the War Committee of the Royal Society, for which he acted as secretary, and the Bridge Stress Committee.

It was only natural that Prof. Dalby's close connexion with railway problems during his service at the locomotive works should direct his attention to the many mechanical problems that arise in steam engine practice, and in the earlier part of his professional career his interest was largely centred on such problems. Towards the end of the nineteenth century, the demand for increased speed of engines brought into prominence the closer study of the methods of balancing rotating and reciprocating masses of engines. Prof. Dalby devoted considerable attention to this problem, and at the spring meeting of the Institution of Naval Architects in 1898 he described a new method which he had devised of solving balancing problems. The advantage of his method was that, by using a 'reference plane', the problem was reduced to one of graphical vector addition. This method he developed in his book "Balancing of Engines", which was first published in 1902. It has received such wide acceptance and has been so generally adopted that its authorship is in danger of being forgotten. In the latest edition of this work (1929) the author rightly states in the preface that his method "has found its way into textbooks with *and without* acknowledgment". Designers of high-speed engines are indebted to Prof. Dalby for so clear and simple a method of solving their balancing problems, and these problems are also not without interest for civil engineers, as the Report of the Bridge Stress Committee conclusively shows. In 1906 he published his second book on engine mechanism, namely, "Valves and Valve Gear Mechanism".

In connexion with the British Association's Gaseous Explosions Committee, Prof. Dalby was associated with the late Prof. H. L. Callendar in attempts to measure directly the temperatures inside the cylinders of gas engines. The method they employed required accurate indicating of the engine, and as the optical indicators then available were not sufficiently accurate for their purpose, Prof. Dalby improved on the design and produced the 'Dalby Watson optical indicator', which gave remarkably fine and accurate indicator diagrams.

Prof. Dalby was not slow to realize that such an indicator would prove invaluable in the rapid testing of materials, and shortly afterwards he designed his 'optical load extension recorder'. In this instrument he measured the load on the test specimen by the elastic extension of a hollow steel weigh-bar, the small elastic extensions being magnified optically to any desired scale. A photographic record of a load extension test could thus be obtained. Inertia effects in such an instrument being practically eliminated, test pieces could be rapidly loaded without sacrifice in accuracy of measurement. To effect such rapid loading he designed a special hydraulic testing machine, and thus he obtained a load extension diagram of a test-piece broken in one second of time. The instrument is described in several papers contributed to the learned societies and also in his book published in 1923, "Strength and Structure of Steel and Other Metals", wherein will be found records of researches carried out by its use.

The largest of Prof. Dalby's publications was "Steam Power". It was published in 1915 and brought into one volume comprehensive studies of steam plants, the properties of steam and the various dynamic and other problems associated with such plant. His last book, published in 1931, was entitled "Power and the Internal Combustion Engine". In addition to the five books mentioned above, he was the author of numerous papers contributed to learned societies and institutions.

In his teaching and lecturing, Prof. Dalby was clear in exposition and could make attractive any subject he presented to his audience. He was wholeheartedly interested in his profession, and his enthusiasm was an inspiration to those who were associated with him. His work at the College and for the many committees on which he served left him little time for recreation, and that recreation he often sought in change of work, for he was always happy at his drawing board designing or improving apparatus for conducting his researches. The many students who have come under his influence, and the wider circle of those who have read his publications or listened to his lectures, will regret the passing of one who has done much for the advancement of engineering science.

WE regret to announce the following deaths:

Dr. H. J. Hansen, of Copenhagen, a foreign member of the Linnean Society of London, on June 26.

Prof. Julius A. Nieuwland, professor of chemistry in Notre Dame University, U.S.A., known for his work on synthetic rubber and lewisite, on June 11, aged fifty-eight years.

News and Views

Royal Society of Edinburgh: Honorary Fellows

THE following have been elected British honorary fellows of the Royal Society of Edinburgh: Sir Charles Boys; Sir Henry Dale, director of the National Institute for Medical Research; Prof. F. G. Donnan, professor of chemistry in the University of London, University College, London. Foreign honorary fellows have been elected as follows: Prof. L. H. Baekeland, honorary professor of chemical engineering, Columbia University, New York; Prof. M. Lugeon, professor of geology, University of Lausanne; Dr. George Sarton, editor of *Isis* and *Osiris*; Dr. G. L. Streeter, director of the Department of Embryology, Carnegie Institution of Washington; N. I. Vavilov, director of the Institute of Genetics, Academy of Sciences, Leningrad; Prof. W. M. Wheeler, emeritus professor of entomology, Harvard University.

Dr. W. S. Bruce Memorial Prize

A COMMITTEE consisting of representatives of the Royal Society of Edinburgh, the Royal Physical Society and the Royal Scottish Geographical Society, has awarded the Dr. W. S. Bruce Memorial Prize to James W. S. Marr, who first went to Polar regions with Sir Ernest Shackleton in the *Quest* in 1921, sailing as a boy scout. On Shackleton's death, the expedition continued under Commander Worsley into the Weddell Sea. Marr next sailed with Commander Worsley in 1925 to Spitsbergen and White Island in the Algarsson expedition. In 1927 he joined the staff of the R.R.S. *Discovery* and since then, with brief intervals at home, he has spent his time in the Southern Ocean, partly in the old *Discovery* and partly in *Discovery II*. From 1929 until 1931 he was in *Discovery* when she was lent to Sir Douglas Mawson for the British-Australian-New Zealand Expedition which found many new stretches of the coast line of Antarctica. Last year Marr published in the "Discovery Reports" a large monograph on the South Orkney Islands, which extended the original researches of Dr. W. S. Bruce on that Antarctic Group.

Dr. F. G. Novy

DR. FREDERICK GEORGE NOVY, formerly professor of bacteriology and dean of the Medical School of the University of Michigan, was presented with the 250,000th microscope produced by Messrs. Bausch and Lomb at a luncheon given to members of the American Association for the Advancement of Science during its summer sessions at Rochester, New York. Dr. Novy was selected for this honour by the executive committee of the American Association, for outstanding research in the field of bacteriology and immunology. He discovered and isolated the *Bacillus Novyi*, the agent of gas gangrene; he was the first to culture *Trypanosoma Lewisi*, and is the discoverer and isolator of *Spirochæta Novyi*, the cause of American relapsing fever. He has also made notable contributions to the study of filterable viruses, the respiratory processes of bacteria, and the causes of diphtheria, yellow fever and bubonic plague. A student of both Koch and Pasteur, Dr. Novy has the distinction of being the only person in the United States to-day who studied under Pasteur. France has made him a Chevalier of the Legion of Honour; Czechoslovakia created him a member of the Order of the White Lion, and Sinclair Lewis has romanticized him in his book, "Arrowsmith". For nearly fifty years, Dr. Novy was a member of the Medical Faculty of the University of Michigan, and is almost the last of the distinguished group gathered together by the late Dean Victor C. Vaughan. Dr. Novy's address at the luncheon, on "Some Results of Microscopic Research of Specific Significance for Human Welfare", was preceded by brief addresses by Dr. Edwin G. Conklin, president of the American Association, Herbert Eisenhart, president of Bausch and Lomb, and Dr. Edward Bausch who presented the 250,000th microscope of the company. It was Dr. Bausch's fifty-ninth year as a member of the Association.

The Use of Knowledge

IN his address at the graduation ceremony of the University of St. Andrews on June 26, Sir James Irvine, referring to the way in which new knowledge is being acquired at a rate much faster than man's capacity to absorb it, and to the way in which the impact of changing conditions has caught us unprepared, suggested that the machinery of Government should include a 'Ministry of Knowledge', the functions of which would be to predict the repercussions of new knowledge on all phases of life. Through such an organization, it might be possible to frame in advance a national policy in which due regard is paid to such far-reaching problems as the future sources of energy, such fundamental questions as to whether our coal supplies are to be used merely for power or as raw material for manufactured products, or whether our forests will be utilized for the purposes for which they were planted or devoted to alternative uses already looming in sight.

UNDOUBTEDLY the rapid diminution almost to vanishing point of the lag between the origin of new knowledge and its application has left man with less time than ever to adapt himself to the repercussions of the new ideas he has evolved. The need for foresight and intelligent anticipation in such matters as the development of industry, transport and town-planning cannot be disputed. While Sir James Irvine's suggestion deserves serious consideration, it is at least doubtful whether the existence of such organized knowledge thirty years ago could have spared the world much of the devastation of unemployment; or whether it is possible to plan in advance when conditions are rapidly changing. Apart from the difficulty of predicting with any accuracy the effect of scientific discoveries on society, the wise use of knowledge involved in planning requires not merely the use of existing knowledge to avoid mistakes committed in the past, but also adaptability, an enlightened opportunism and a readiness to examine all matters in the spirit and method of science. It is, however, a hopeful sign that leaders of scientific thought are to an increasing extent concerning themselves with the consequences of the application of scientific discoveries. Organizations such as the Scottish Development Council and the National Trust, cited by Sir James, already exist for the wise use or conservation of our national resources, and they deserve the support of all who are in any measure equipped to guide opinion and direct progress.

Social Economics in the University of Manchester

THE Council of the University of Manchester has announced its decision to revive the second chair in the Faculty of Commerce and Administration, which has been in abeyance since 1932, with the title of "Chair of Social Economics". Mr. John Jewkes, who has been in charge of the Economics Research Section of the Faculty, which has been responsible for such important investigations as the industrial surveys of Lancashire and also Cumberland and Furness, undertaken for the Board of Trade, and the study of juvenile unemployment, has been elected to the chair as from September next. The duties will include the conduct of research and supervision of the work in the Economics Research Section, the creation of which was a new development in Great Britain in the organization of economic research within a university. It has now passed the experimental stage, and Mr. Jewkes's appointment is a recognition of it as an integral and permanent part of the work of the Department of Economics at the University of Manchester. Among a number of important inquiries which are in hand may be mentioned a study of the case histories of 2,000 juveniles in Lancashire who left school at Easter 1934; a study of the location of British industry, the changes proceeding and the forces behind them; a re-assessment of the industrial situation in Lancashire, being carried out at the invitation of the Lancashire Industrial Development Council; and a study of the systems of wage payment and labour conditions in the Lancashire cotton-weaving industry.

Manganese and Plant Growth

MANGANESE is now recognized as an essential element for normal plant growth, and most soils contain sufficient of it in an available form to supply the needs of all vegetation. There are certain soils, however, mainly reclaimed swamp soils and soils with a very high calcium carbonate content, in which manganese is either not present in sufficient quantity, or not in an available enough form, to support the growth of certain crops. Characteristic diseases then result, of which the best known are the grey speck disease of oats, a disease of beet in Holland, chlorosis of spinach on Long Island and diseases of tomatoes and other crops on the Everglade soils of Florida, although in the last case deficiency of copper appears to be concerned as well as of manganese. The availability of the manganese in the soil is influenced to some extent by weather conditions and by cultural practices. In general, dry conditions aggravate the diseases, and also manurial treatments, such as liming, which tend to make the soil more alkaline. In Denmark a formula is now used, known as the 'manganese value' (Steenbjerg, Trans. Third Int. Congr. Soil Sci. Oxford, 1935), which is based on a determination of the exchangeable manganese by leaching with magnesium nitrate, and on a factor which is a measure of the energy displayed by the soil colloids in keeping the exchangeable manganese. It is advocated that the manganese value of a soil should always be determined before liming, especially in the case of sandy soils, so that a calculation can be made of the largest allowable increase in pH which would not entail danger of grey speck disease. In the same report, Gerretsen claims that the symptoms of manganese deficiency are largely the result of the absorption of toxic products from bacteria which multiply more profusely on the roots of manganese-deficient plants.

Eastern Frontiers of the Roman Empire

SIR AUREL STEIN has made an offer to the authorities concerned to make a detailed survey of that part of the eastern frontier of the ancient Roman Empire which lies within Transjordania and Iraq. It will be necessary that a great part of this survey should be carried out from the air, as many of the sites are situated in the desert, and can be located only by this method. The proposal has the support of the British Academy and the Society of Antiquaries of London. It will form part of the scheme for the complete survey of the Roman Empire on a scale of 1 : 1,000,000, for which the British Ordnance Survey has already accepted its share of responsibility. The French have now completed the survey of that part of the frontier within the mandated territory of Syria. The survey was made by the French Air Force acting in conjunction with the Académie des Inscriptions et Lettres, and records observations of ancient roads, forts and defensive posts, as well as water supply. It is proposed that similar observations should be made in the survey projected by Sir Aurel Stein.

Racial Elements in Sumerian Art

ARCHÆOLOGISTS at times may seem over-bold in attributing racial values to the terms of their cultural analyses, although the practice frequently has much to be said in its favour, when it is followed, with due reservation, as a convenient form of shorthand while a question of origins is still in suspense. Sir

Leonard Woolley's lecture on "The Racial Elements in Sumerian Art History" before the Royal Society of Arts on February 19 (*J. Roy. Soc. Arts*, **84**, April 3, 1936) afforded an example of the pregnant inferences to be drawn from study of the geographical distribution of cultural elements to be related to those found at Ur and kindred sites in Mesopotamia in its bearing on the solution of the racial problem in Sumeria. As he pointed out, various theories have been put forward at different times, as knowledge has grown, to interpret evidence of the physical characters of the early population of Sumeria. Sir Leonard himself, by citing specific elements which go to make up the complex of Sumerian art, was able to show that it is a compound of three cultural streams. Of these the Asianic or Iranian goes back at Ur to pre-diluvial times, its most marked characteristics there being the painted pottery, while it extends from Mesopotamia to China; a second is derivative from Anatolia and the third comes from northern Syria. In these three cultural elements he finds, hypothetically, a parallel to the distinction which is drawn in the evidence for three differentiated physical types in the population. In this instance, it is to be admitted, there would appear to be good ground for the view put forward that the brilliant achievement of Sumerian art, in which these cultural streams unite, was due to that cross-fertilization of racial strains, which Sir Leonard maintains lies at the root of all great achievements in the art of a people as a whole. It is to be expected that Sir Leonard's new field of exploration in northern Syria will throw further light on the racial as well as the cultural problem.

Roman Leicester

EXCAVATION of Roman remains at Leicester now in progress has resolved an archæological doubt of long standing. While instructed opinion has hesitated between identifying the well-known Jewry wall, one of the highest surviving Roman walls in Britain, popularly regarded as a temple of Janas, as a Roman bath building, a basilica or even a town gate, it has now been shown, according to a report in *The Times* of July 4, to be part one of the external walls of the basilica in the forum of Roman Leicester, dating probably from about A.D. 100. A large part of the adjacent site, until recently occupied by a factory, is being cleared by the Corporation for the erection of public baths, and advantage has been taken of the opportunity to carry out these excavations. The base of the Jewry wall has been uncovered to some ten feet below the present surface, giving a total height of existing masonry of more than thirty-five feet. Two arched openings, previously thought to be doorways, are now revealed as windows. Beneath the Jewry wall, timber and masonry are associated with pottery and coins going back to the earliest Roman occupation of Britain. To the west of the wall is emerging a courtyard about 175 ft. wide, flanked by ranges of rooms or shops opening on to the courtyard by porticoes. This is the forum, of which the basilica forms part. Fronting the forum and abutting centrally on the basilica are the massive foundations of an architectural feature, probably once surmounted by a pediment, which dominated the forum and faced the main entrance. Outside the northern wall of the forum a stretch of cobbled roadway, deeply scored by wheels, has been uncovered. Massive walls and fragments of columns found on the factory site some years ago may now be identified as fragments of the forum and its colonnades. The road on the southern side of the forum is largely covered by St. Nicholas Street, near which is preserved one of the mosaic pavements for which Roman Leicester is famous. The excavations are being carried out by Miss Kathleen Kenyon under a committee, of which the Duke of Rutland is president, in co-operation with the Corporation of Leicester.

Electricity Distribution in Great Britain

THE report of the Committee on Electricity Distribution has now been published (Ministry of Transport. London: H.M. Stationery Office. 2*s*. net). The chairman was Sir Harry McGowan, and Sir John Snell was a member of the Committee. The evidence, some of which was conflicting, has all been carefully considered, and definite recommendations are given which seem thoroughly justified. The Committee does not suggest nationalization or the setting up of a Distribution Commission. It advises a reduction in the present number of undertakings by amalgamating the smaller and less efficient stations with the larger ones. It is stated that any attempt to carry through a scheme of re-organization on a voluntary basis is bound to fail, and legislation must confer definite and adequate compulsory powers. The schemes of re-organization should make provision for the possibility of ultimate public ownership of all undertakings, including those not at present subject to purchase by the local authorities. It is proposed that no undertakings should be transferred compulsorily under a scheme of re-organization without a prior local investigation. To this end the Electricity Commissioners should be empowered to delimit the country into a number of areas and to appoint for each area a temporary district commissioner, with such technical and financial assistance as may be necessary. The district commissioner would bring under review all electric undertakings in his area. The Electricity Commissioners, after publishing a scheme and considering any representations, should be empowered to approve it and, if agreed, it should become operative at once.

WITH regard to the London and Home Counties Electricity District, which covers an area with a large number of undertakings, some with duplication of powers, many with differing systems and tariffs, and offering very unequal facilities, the criticisms recently made by the public are often justified. A substantial measure of amalgamation and co-ordination is possible and necessary. The present constitution of the London and Home Counties Joint Electricity and Authority should be brought under review. Complete standardization of systems and voltages should be the ultimate objective, but it is difficult to see how this can be done equitably. The amalgamation of undertakings into a smaller number of larger undertakings is an important step towards standardization of methods of charging and more uniform prices. The Minister of Transport should be empowered to require all undertakers to offer an improved statutory two-part tariff for domestic supplies, as an optional alternative to a flat-rate charge. The fixed charge under an approved two-part tariff should be based either on the floor area of the house or on its rateable value, and all undertakers should be required to publish the actual scale of fixed charges under their two-part tariff. If these suggestions were adopted there should result a general, though necessarily gradual, reduction in costs. Amongst other recommendations, it is suggested that where gas and electricity undertakings are left under the joint ownership of a local authority, it would assist in the more rapid development of the electricity undertaking if the authority were required to have separate committees. Evidence was given which showed that restrictions had been imposed on the development of the electrical undertaking in order to prevent the financial position of the gas undertaking from being adversely affected. Both public activities should be equally untrammelled.

Meteorology in India

IN the Report on the Administration of the Meteorological Department of the Government of India in 1934–35 (Delhi: Manager of Publications, 1935), an account is given of an important change in the arrangements for dealing with the increasing meteorological requirements of aviation along the trans-India air route. In previous years, a separate forecast had been issued to each aircraft in respect of the route covered by it each day from the forecasting centre concerned; but it became evident that it would soon be impossible for the two centres at Karachi and Calcutta to continue to do this for the four thousand miles of the route between Bahrein and Victoria Point. Arrangements were therefore made to broadcast forecasts for each section of the route regularly at fixed times, and to distribute data relating to upper winds and cloud height by wireless from pilot balloon stations along the trans-India route twice daily. The Agricultural Meteorology Branch carried out a number of researches, mainly at the Central Agricultural Meteorological Observatory, Poona; instruments for the study of microclimatology were designed and tested, and a number of papers were written dealing with the correlation between meteorological conditions in the open and among growing crops; researches into evaporation, percolation and effective rainfall were also made. Experiments on the effect on soil temperature of a thin covering of soil of different colours and from different districts showed that coverings of certain soils had a big effect on the climate of the soil beneath. Other investigations were made into the albedo of different types of soil and vegetation. The scheme of crop-weather precision observations was applied to wheat and jowar at Poona, to rice at Karjat and to bajri at Baroda. The study of frost damage and methods of preventing it was also included in this branch's activities. The Upper Air Observatory at Agra released seventy-seven sounding balloons with recording instruments, and nearly half of these were recovered.

Physiology of Indian Crop Plants

FOR some time past, the staff of the Institute of Agricultural Research of the Benares Hindu University has been engaged, under the leadership of Prof. B. N. Singh, in detailed and comparative studies of the physiology of Indian crop plants. A considerable number of publications on this subject has now been issued, mainly in the *Proceedings of the Indian Academy of Sciences*, and good progress has evidently been made in a highly interesting and important field of work. The most extensive work completed is that dealing with photosynthesis under different conditions of light, temperature and carbon dioxide supply. Since a large part of previous research on this subject has been carried out in temperate climates, it will be obvious that detailed studies of tropical plants are likely to be of considerable value. One striking result of this work is that tropical plants are found to have a higher light requirement in photosynthesis than similar species grown under temperate climatic conditions. Another especially interesting problem under investigation is that of the differences in respiration rate found to exist in plants differing in their duration of life. Short-lived plants are apparently characterised by a low respiration rate, which also falls off very rapidly as the age of the plant increases. Long-lived plants, on the other hand, not only have a high respiration rate but also are able to maintain this higher rate throughout life. Other subjects under investigation by comparative methods include the water requirements of seeds possessing different structural and biochemical properties, and the effects on plant growth of irradiating seeds with X-rays.

Electricity in Horticulture

ELECTRO-CULTURE has to take into account the effects of electric heating, electric lighting and the voltage stress on the life of plants. The first application of electricity took the form of high-voltage discharges produced in close proximity to various plants in an endeavour to obtain artificial stimulation. In the Engineering Supplement for May of *Siemens Magazine*, a survey is given of recent developments, and the photographs shown of the effects produced are convincing. It has often been noticed that an increased growth of crops sometimes occurs during thundery weather. In the Arctic, where the average atmospheric potential gradient is high, it has been observed that the growth of vegetation during the short summer is more vigorous than in southern climates. Experiments have been carried out on cereals, potatoes, beets, tomatoes, strawberries and raspberries, and increases up to forty per cent have been obtained. Electricity in the form of light was the next application in the aid of horticulture. For vigorous plant growth a minimum of about 4 hours of sunshine and altogether about 10 hours of daylight per day are required. As an example of the effect obtained by providing lighting for 10 hours each night with an illumination of about 4 foot candles, pansies after 83 days gave an average of approximately 16 flowers per plant as against 2 flowers for unlighted plants; and asters after 157 days' treatment bloomed 33 days earlier than usual. The red-yellow rays accelerate growth by stimulating the chlorophyll and the absorption of carbonic acid. Electric cables are also described which are used for heating the soil, and excellent economical results have been obtained.

Ancient Heating and Lighting Appliances

ONE of the world's largest collections of heating and lighting appliances has recently been presented to the Smithsonian Institution together with an endowment for its maintenance. It begins from the fire drills with which primitive peoples started a flame by friction, and goes on to some of the latest appliances for lighting and heating. A description of the collection has been issued by the Smithsonian Institution. After the fire drill, the account passes to the percussion method, in which a hard stone, such as flint, gives a spark when struck against steel. The steel used was frequently made in an artistic form, and was called a 'briquet'. Some of these briquets dating from about A.D. 500 were unearthed in a farm in France in 1902. One specimen is inlaid with gold, and has bits of ruby-coloured glass embedded in it. There are also pistol-action lighters, which employ the principle of the flint and steel but simplify it by means of a trigger. This way of starting a fire came into general use about 1700, and was developed from the flint-lock gun, the first of which appeared in England about 1626. Illustrating the period preceding matches, when light was obtained by chemical action, the collection contains a Döbereiner jar, introduced about 1823. Flame was produced by letting hydrogen come into contact with certain other substances. The lamps range from one about the size of a thumb to another as tall as a man. The latter was obtained from a Buddhist temple. Another curiosity is a rolling lamp which was used at Hindu weddings; the light remains upright when the globe is rolled along the ground. There is also a horological lamp which tells the time of night by the amount of oil consumed.

Anti-Vivisection Finance

THE honorary treasurer of the Research Defence Society, Sir Leonard Rogers, in a recent issue of the *Fight Against Disease* (**24**, No. 1) directs attention to the sums spent on propaganda by anti-vivisection societies within recent years. Analysing the certified annual accounts from 1912 onwards, and making allowance on one side for missing reports, and upon the other for useful work for animals done by some societies, it is estimated that a sum of approximately £600,000 has been received for 'anti-vivisection' work, and nearly £500,000 expended. The success in raising funds, in spite of the verdicts of two Royal Commissions against them, would appear to be partly due to a facile appeal to sentiment, aided by the lack of adequate medical and scientific knowledge of the masses to enable them to sift the 'anti-' statements. Anti-vivisection propaganda has sought to curtail the work of hospitals and veterinary colleges, and the one piece of useful work that might have been accomplished with the huge accumulated funds, the support of the 'Anti-Vivisection Hospital' at Battersea, has been allowed to lapse.

Prevention of Disease in the Tropics

A MEETING of the Industrial Advisory Committee of the Ross Institute (London School of Hygiene and Tropical Medicine) was held on April 16 under the chairmanship of Mr. G. H. Masefield, when reports were received upon the Institute's activities in India, Ceylon, and South, East, and West Africa. Malaria prevention has received much attention, and instances were given of the value of mosquito control in combating this disease. Other diseases, including yellow fever and the eye-fly pest of India and Ceylon, were also discussed. Allusion was made to the value of reinforced aluminium foil as a heat insulator; in a tea factory in Ceylon a reduction of temperature of 7° F. at noon in the rolling room had been obtained by its use.

British Medical Association: Annual Meeting

THE one hundred and fourth annual meeting of the British Medical Association will be held in Oxford on July 17–25, under the presidency of Sir E. Farquhar Buzzard, regius professor of medicine in the University of Oxford. The meeting will be divided into the following sections under the presidents indicated: Medicine (Dr. A. G. Gibson); Surgery (Prof. G. E. Gask); Obstetrics and Gynæcology (Prof. H. Beckwith Whitehouse); Ophthalmology (Dr. P. E. H. Adams); Pathology and Bacteriology (Dr. E. W. Ainley Walker); Anatomy (Prof. W. E. Le Gros Clark); Diseases of Children (Dr. R. C. Jewesbury); Neurology and Psychological Medicine (T. S. Good); Orthopædics (G. R. Girdlestone); Oto-Rhino-Laryngology (L. Golledge); Pharmacology and Therapeutics, with Anæsthetics (Prof. J. A. Gunn); Physical Medicine (Dr. W. J. Turrell); Physiology and Biochemistry (Prof. R. A. Peters); Radiology (R. H. Sankey); Tuberculosis (Dr. W. Stobie); Dermatology (Dr. S. E. Dore); History of Medicine (Dr. A. Chaplin); Medical Sociology (Sir George Newman); Nutrition (Dr. A. F. Hurst); Public Medicine (Dr. W. M. Willoughby). A popular lecture, entitled "Anthropology and Medicine", will be delivered on July 24 at 8 p.m. by Dr. R. R. Marett. In addition to the usual professional exhibitions, an exhibition of pictures illustrating the history of Oxford medicine will be open at the University Museum from July 20 until July 25. Further information can be obtained from the Secretary, B.M.A. Office, The Cottage, Keble Road, Oxford.

Announcements

AT the annual meeting of the Royal Anthropological Institute, the following officers for the year 1936–37 were elected. *President:* Dr. H. S. Harrison; *Vice-President:* Dr. H. J. Fleure; *Hon. Secretary:* Dr. R. W. Firth; *Hon. Treasurer:* H. Coote Lake; *Hon. Editor:* R. U. Sayce. The Rivers Memorial Medal for 1936 was awarded to Prof. Peter H. Buck (Te Rangi Hiroa) for anthropological work in the allied fields of New Zealand, Central and Eastern Polynesia. The Wellcome Gold Medal for 1935 was awarded to Dr. Lucy Philip Mair for an essay entitled "An Anthropologist's Estimate of African Policies".

THE following appointments in the Colonial Service have recently been made: P. F. Mason, to be assistant conservator of forests, Nigeria; J. C. K. McElderry, to be assistant conservator of forests, Nigeria; M. L. Pattullo, to be assistant conservator of forests, Nigeria; R. G. M. S. Macgregor, to be professor of physiology, Malaya; W. Orr, to be veterinary officer, Malaya; A. L. Craig-Bennett, to be chief fisheries officer, Palestine; A. H. S. Megaw, to be director of antiquities, Cyprus; F. P. Jepson, controller of plant pests and assistant entomologist, to be deputy director of agriculture, Ceylon; D. E. Wilson, medical officer, to be pathologist, Medical Department, Tanganyika.

PROF. JEAN SABRAZÈS, professor of pathological anatomy and clinical microscopy in the University of Bordeaux, has been elected *Correspondant* for the Section of Medicine and Surgery of the Paris Academy of Sciences, in succession to the late Prof. Léon Fréderícq.

AN institute for the investigation of rheumatism, the first of its kind in Austria, has been founded at Baden near Vienna. A balneological investigation department will be added later. The honorary director of the institute is Prof. R. Ewald.

THE Soviet Government has decided to erect a monument to the late Prof. Pavlov as well as to name an institute after him and to publish his works in four languages. His brain is to be preserved in the Moscow Institute for Cerebral Research, and his widow is to receive a pension of 1,000 roubles monthly.

THE ninth International Dental Congress will be held in Vienna on August 2–8 under the presidency of Dr. Hans Pichler, and will consist of fifteen sections. Further information can be obtained from Mr. A. E. Rowlett, 165 London Road, Leicester.

THE prefecture of Tokyo is to found a museum of hygiene, the inauguration of which is to coincide with the celebration of the 2600th anniversary of the Japanese era in 1940. The Society of School Hygiene at Tokyo proposes to organize on this occasion a general meeting, and to undertake active propaganda in favour of school hygiene.

IN order to permit more time for the preparation of material, the First International Conference on Fever Therapy, originally arranged to be held in New York on September 29–October 23 (see NATURE, 137, 989, 1936), has been postponed until March 30–April 2, 1937. Further information can be obtained from Dr. William Bierman, 471 Park Avenue, New York City, U.S.A.

A COMPETITION was held some time ago by the 'EPIDOS' (International Association of Bone Glue Manufacturers) with the object of stimulating research in the increase and improvement of outlets for bone glue. Several promising ideas were put before the Association. A total sum of 30,000 Swiss francs was distributed to the winners of this competition. EPIDOS has decided to continue its investigations in this direction. It has set aside a certain sum for the purpose of encouraging research by those who will put forward interesting ideas for the use of glue, and also recompensing those with proposals already ripe for development. Further information can be obtained from the General Secretariat of the International Association, 40 Rue du Colisée, Paris.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A teacher of general elementary science and mathematics in the Technical College, Wolverton—The Principal (July 13).

A lecturer in mechanical engineering in the Walsall Technical College—The Director of Education, Education Offices, Council House, Walsall (July 16).

A head of the Applied Mathematics Department in the Rochdale Municipal Technical School—The Principal (July 16).

An assistant in the Science Department (zoology and botany) in the Barnsley Mining and Technical College—The Principal (July 18).

Two University demonstrators in anatomy in the University of Cambridge—Dr. Roughton, Department of Physiology (July 19).

An assistant lecturer in electrical engineering in the Imperial College of Science and Technology (City and Guilds College)—The Secretary, Imperial College of Science and Technology, Prince Consort Road, S.W.7 (July 24).

An assistant inspector (Grade 2) in the Aeronautical Inspection Directorate of the Air Ministry—The Secretary (S.2.d.), Air Ministry (July 25).

An assistant director of research in medicine in the University of Cambridge—The Regius Professor of Physic (August 1).

A general manager of the Dudley Zoo—The Secretary, Dudley Zoological Society, Ltd., The Earl of Dudley's Estate Offices, Dudley, Worcs. (August 1).

A University reader in mathematics in the Imperial College—Royal College of Science—The Academic Registrar, University of London, S.W.7 (August 21).

A professor of biology in the University of Otago—The High Commissioner for New Zealand, 415 Strand, London, W.C.2 (August 31).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 81.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Corona during the Total Solar Eclipse of June 19

OUR small amateur party (Miss Gerasimova and I) had an opportunity of observing the total solar eclipse of June 19, from the eclipse camp at Ak Boulak (near Orenburg, U.S.S.R.). The expedition of Poulkova Observatory and that of Harvard University conducted their work there.

For taking photographs of the total phase, we had two reflecting telescopes equipped with parabolic mirrors, which were ground, polished and figured by myself. The installation was a most primitive one. No guiding mechanism was available; consequently, only short exposures (from half a second to one second) could be used in order to obtain good definition.

Atmospheric conditions were splendid, which was an agreeable surprise to us, since the weather was very poor during three preceding days. To see the eclipse, thousands of people gathered on the hill where the camp was situated. Many of them came from Orenburg and even from farther distant localities.

The magnificent panorama of the total eclipse was opened to our eyes at the expected moment. The sky became of deep steel tint with a conspicuous shade of lilac. Venus appeared on the right upper side quite close to the sun; between the two, Mars was clearly seen. The horizon was orange red. The singing of skylarks seemed louder in the profound silence.

The corona was unusually bright; it emitted apparently more light than the full moon. Its colour could be described as silvery and silky. The shape of the corona was typical of the period of high activity of the sun, and somewhat reminded us of a five-pointed star. Two prominences of a bright ruby colour could be easily seen by the naked eye at the edge of the velvety black disk of the moon.

The photograph reproduced here (Fig. 1) was taken directly in the focus of our six-inch mirror (140 cm. focal distance), and gives some idea of the appearance of the inner corona viewed through a low-power telescope; in reproduction it has been enlarged about 5 diameters. This photograph was taken shortly after the beginning of the total phase. A second was taken somewhat after the central moment, and the third a few seconds before the end of the total phase. Prominences are very conspicuous on all the photographs; the greatest of them attains the height of at least 100,000 km.

The duration of the total phase was almost two minutes, a period of time sufficient for making more than three photographs, even with our primitive equipment. However, we were able to make only three exposures; the precious instants were gone surprisingly soon. This psychological effect should be undoubtedly attributed to great excitement caused by viewing this rare natural phenomenon.

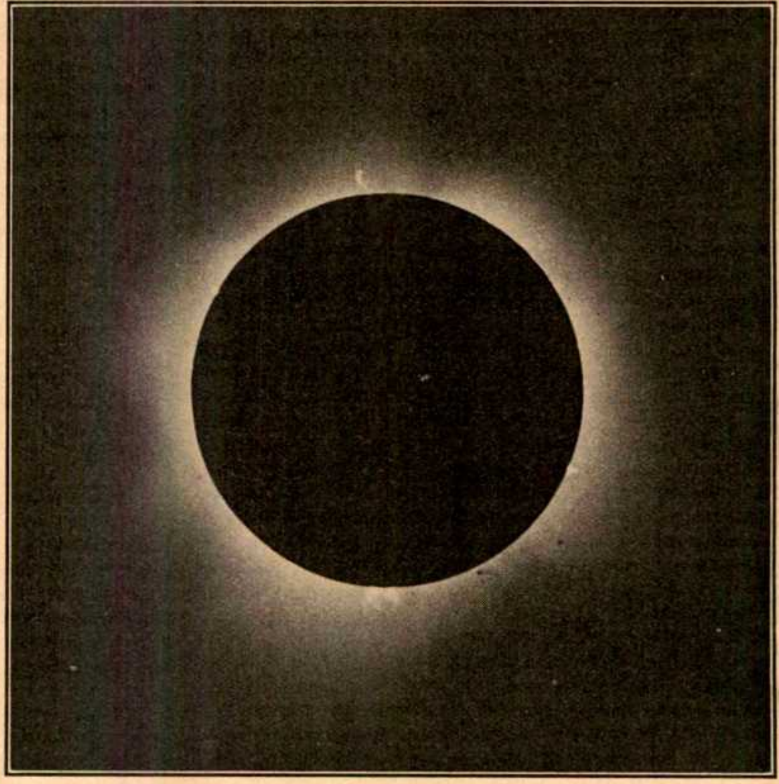

FIG. 1. Total solar eclipse of June 19, photographed at Ak Boulak.

Thanks are due to Prof. B. P. Gerasimovič, head of the Expedition, for admitting us to the Ak Boulak eclipse camp.

M. NAVASHIN.

Moscow.

The Nature of Viscid Fluid Threads

THE considerations which follow gained the interest of Sir William Hardy, a specialist in such matters, when discussed with him briefly not a few years ago. As I am not aware of any record, at any rate in reasonably simple form, I venture to submit a brief statement.

The fact that permanent viscid threads can be pulled out of a plastic mass, after the manner of fibres of silk or of rayon before they solidify, does not lose its mechanical mystery through familiarity. If such a thread is suspended from one end, which oscillates up and down, it expands and contracts in length over a large range in dynamical unison with the oscillation, without breaking. The great amplitude may be imagined as due to the effective molecules being shaped like long dumb-bells, such as naturally interact mainly by force between their ends. If two rows of them lie parallel, there is a position of equilibrium when the ends are opposite each other. If one row is slid along, an elastic reaction comes into play which increases to a maximum, then diminishes as the attraction of the next pole becomes important, until it vanishes, when each attracted pole in the row is equidistant from the two influencing ones. This is an intermediate unstable position.

This peculiar complex type of viscid alternating elasticity holds a possible key to one type of phenomena: the expansion consists of rows of molecules within the threads sliding past one another, thus permitting reversible extension of large range without rupture in a way which we need not here follow in detail. The ruling idea came from the theory of the homologous hydrocarbon series provided by organic chemistry in its very early days, giving dumb-bell pictures which were then taken to be symbolic, but now under the scrutiny of X-ray diffraction reveal a geometrical reality.

A similar, but much less definite multiplication of basic molecular elements, is actually formed in hyper-molecules of substances of cellulose type, such as the plastic threads would require. But how is it that the parallel rows are not dispersed sideways from one another? Observe a hanging thread: it shrinks up at the free end into a spherical blob, like a dew-drop, obviously by surface tension holding it firm; higher up the length-wise surface tension has to hold up the lower part of the thread against its weight, while the transverse tension round the section holds the thread together. The section changes during an imposed vibration, the supporting force thus altering rhythmically as required. There is room for a mathematical theory here, if enough is known of the facts.

A somewhat cognate subject is the tension theory of the foreign monomolecular surface-layers discovered by Miss Pockels of Heidelberg and the late Lord Rayleigh, and developed extensively mainly by I. Langmuir and N. K. Adam. But one may insist that this effect is superposed on the Young–Laplace theory of an intrinsic surface tension at a pure interface and by no means replaces it.

One recalls also another cognate subject. Among my early recollections is the vision of Lord Kelvin standing, cup and saucer in hand, orating on the wisdom of the technique of the ladies' tea table, which spread a film of water in the saucer to prevent the cup of tea sliding over it. For, as he insisted, this brings a new type of intimate friction, entirely different from the smooth viscosity developed into hydro-dynamic theory by his friend and prophet Stokes, a theory which was to receive so vast expansion into the practical realms of ship-resistance and lubrication largely in the hands of Osborne Reynolds. All these topics, so simple in essence, now ramify very extensively throughout the most recent marvellous technology, with no slight reaction backward on abstract science.

Inactivation of Crystalline Pepsin

CRYSTALLINE pepsin, in solutions of constant ionic strength on the alkaline side of its stability maximum, inactivates unimolecularly at a rate which is inversely proportional to the *fifth* power of the hydrogen ion concentration. This unusual relationship has been demonstrated over a velocity interval of 1 to 5,000 in nearly a hundred kinetic experiments at two temperatures with four different buffers. The rate varies with the buffer, but the fifth-power relation does not. As the buffer ratios change by different amounts in the same *p*H range, general basic catalysis is therefore excluded. It is likewise improbable that simple hydroxyl ion catalysis determines the rate.

The dependence on ionic strength is striking. Between $\mu = 0{\cdot}012$ and $\mu = 0{\cdot}10$, the velocity at constant *p*H increases by more than thirty times, regardless of the mono-monovalent salt used. At higher concentrations the change is smaller and finally reverses. The effect is complex, since the curve relating log-velocity to *p*H is shifted along both axes. Various relations to acidity earlier described[1] are partly fortuitous, owing to failure to control ionic strength.

This description applies only when the solutions are not agitated. On shaking, a heterogeneous reaction, independent of *p*H and μ over wide limits, obscures the results. The fifth power appears only at *p*H above 6·2 ($\mu = 0{\cdot}1$), where the homogeneous reaction is rapid enough to predominate. In more acid solutions the half-period of the latter may exceed five years at 25°.

The large exponent probably indicates that equilibria governing the concentration of an unstable species of pepsin ion determine the rate. Five acid groups must dissociate in the formation of this ion; the dissociation of the strongest group must also be fairly small in this range of acidity. Pepsin contains a limited variety of widely-spaced acid radicals; thus, it is conceivable that the five groups are alike and possess nearly identical dissociation constants. If they differ only by limiting statistical factors, the failure of the fifth-power dependence to hold exactly at *p*H above 6·45 means that the dissociation constants are near $1{\cdot}7 \times 10^{-7}$. This is slightly stronger than the positively charged ammonium groups in the simpler polypeptides[2] and in a simple protein[3], and approximately correct if the free amino groups of pepsin come from cystine rather than lysine. There are probably just five cystine residues in the enzyme, but Herriott and Northrop find four rather than five primary amino groups in pepsin[4].

If account is taken of the effect of temperature on the size of the pepsin fraction present as the unstable ion, the temperature effect on the rate of the actual reaction (decomposition of this ion) is much smaller than the observed change in velocity. When the ratio $k_{25°}/k_{15°}$ (about 30) is used to calculate the critical increment, the result is 64,000 calories—a high figure, characteristic of protein denaturation. When the shift in the pH dependence is allowed for (assuming all five groups alike) a quite ordinary value, 20,000 calories, is obtained. The exponent produces a large disparity, though the heat of dissociation of each group is only 9,000 calories. The latter value is favourable to the view that primary amino groups are involved, if the possible complications of tautomerism may be neglected. (Michaelis and Rothstein concluded that temperature changes only bring about changes in hydroxyl ion concentration. This unwarranted conclusion depends on the assumption that the inverse kinetic relation to hydrogen ions signifies a direct dependence on hydroxyl ions.)

Should this procedure apply to proteins generally, the statistical-mechanical difficulties arising from the great temperature effect in denaturation may prove to be illusory. The frequently observed variation of critical increment with pH, and its decline to a limiting value at high temperatures, can also be explained.

These measurements, to be described in detail elsewhere, owe much to the generous interest of Prof. J. N. Brønsted.

The Nitroprusside Reaction as a Test for Reduced Glutathione

THIS test was first introduced by Morner[1]. He added sodium nitroprusside and then alkali to cystein and obtained a deep purple red. This changed into a reddish brown and finally disappeared. Cystin gave no reaction. Mörner used a solution of pure cystein, and whether or not he heated his solution prior to the test he did not state. Heating in this case would not affect the results materially. In 1921 Hopkins[2] very casually suggested heating tissue in weak acetic acid in order to intensify the reaction before applying the test. This unchallenged suggestion has led other workers to heat tissues with acetic acid prior to the application of the test, thus obtaining wholly meaningless results (see, for example, Fink[3], Camp[4] and Coldwater[5]). In 1923 Harris[6] showed that native proteins which are non-reactive to nitroprusside become reactive when warmed with acid or base. For example, fresh ovalbumin is placed in three test-tubes and to tube *A* nothing is added; to tube *B* acetic acid is added; and to tube *C* acetic acid is added, and this tube is heated. All tubes are rendered alkaline with ammonium sulphate. The nitroprusside test is then negative in tubes *A* and *B* and positive only in the tube that was heated. Heat denatures proteins and liberates free $-SH$ radicals if the protein contains such in combined form.

Coldwater allowed tadpole tails to regenerate for 14 days, applied the nitroprusside test, and found that the regenerating part gave a more intense colour. I allowed tails of overwintering tadpoles (*Rana clamitans*) to regenerate for 3 weeks at 13°–16° C., keeping the animals without food. The tips, *C* (Fig. 1), of the tails were analysed quantitatively for GSH as soon as cut. After the elapse of the given time for regeneration (at the end of which the tails were less than half regenerated) regions *A*, *B*, and the regenerated region *R* were analysed for GSH. Two series of 35 tadpoles in each were analysed. The results are indicated in the accompanying table and are expressed in percentages of wet weight.

Per cent GSH of wet weight of different regions of a tadpole's tail

Series	Region of tail			
	A	*B*	(Regenerate) *R*	*C*
I	0·028	0·024	0·021	0·025
II	0·033	0·021	0·016	0·030
Average	0·030	0·022	0·018	0·027
Probable Error	± 0·001	± 0·0006	± 0·001	± 0·001

It is clear that the regenerating area has a lower concentration of GSH than the non-regenerating muscular regions. If the bone present in the old portion of the tail were removed, or if the results were reckoned in terms of dry weight, the differences would have been even greater. These results, of course, in no way contradict any hypotheses put forward by others that the $-SH$ radical may be a factor in regeneration, since the amount of GSH necessary for muscle metabolism might be far in excess of the small amount required for regeneration. This work does show, however, the fallacious results obtained by heating tissues prior to the application of the nitroprusside test.

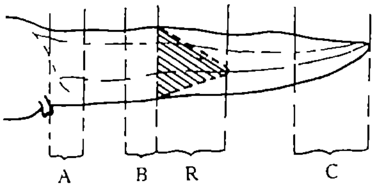

FIG. 1. Tail of *Rana clamitans* tadpole. *A*, *B* and *C* are the regions of the old tail analysed for GSH. *R* is the regenerating area.

The nitroprusside test was applied to pieces of *Euplanaria maculata* at different time intervals after cutting (2, 3, and 7 days). The initial result was an intense purple red throughout. Fading began in the lateral and regenerating areas of the reconstituting organism. If the permeability factor was not completely eliminated by acetic acid, then the areas shown to be more permeable to methylene blue stained first (that is, the lateral areas and the regenerating tissue). The other tissues stained later, but just as intensely, and the colour disappeared later. The intensity of colour was not at a maximum at the same time throughout the animal. Incidentally, it may also be mentioned that the nitroprusside reaction was applied to *Hydra grisea*. The immediate result was an initial flash of colour of about equal intensity throughout. The colour in the tentacles and in the stalk faded out at a very definitely earlier period than that in the main body region. Prior to the test, the animals were chloretonised and were in an expanded condition. Coldwater's results can easily be interpreted as due to differences in penetration of the reagents in the regenerating and non-regenerating regions.

The specificity of the nitroprusside test for reduced glutathione in living tissues has also been questioned. Now Sullivan[7] noted that, apart from free cystein, substances giving a positive nitroprusside test are not present in normal tissues. These substances include acetone, ethyl aceto-acetic acid, and cyanacetamide. There is, moreover, no authentic record indicating the presence of free cystein in living tissues. Applying Sullivan's test for cystein, Tunnicliffe[8], Thompson and Voegtlin[9], Gregory and Goss[10] and I failed to find free cystein in living tissues. It may thus be concluded that the nitroprusside test is specific for reduced glutathione *when applied to normal living tissues and when ammonium hydroxide is used as the alkali and no heat is applied.*

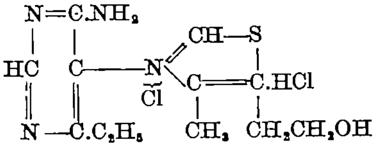
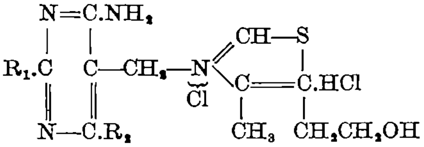
The Structure of Aneurin and Thiochrome

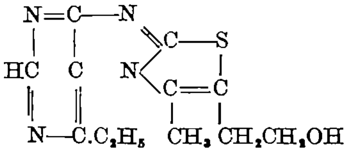
R. R. WILLIAMS has just published[1] a note on the structure of aneurin (vitamin B_1). From a study of degradation products of the vitamin, he concludes that his original formula (I)[2] for aneurin is wrong, and that it should be represented by (II: where $R_1 = CH_3$; $R_2 = H$); this new structure is similar in essentials to that suggested on theoretical grounds by K. Makino and T. I. Imai (II: where $R_1 = H$; $R_2 = CH_3$)[3].



I



II



III

For thiochrome, which is formed from aneurin by mild oxidation, we suggested on the basis of formula (I) the structure (III)[4]. In the course of subsequent synthetic work we observed that thiazpurines, prepared as models for a thiochrome synthesis, although blue fluorescent in ultra-violet light, never showed fluorescence in daylight. This led us to suspect that (I) might not represent aneurin, and our suspicion was confirmed on completing the synthesis of the compound having structure (I). The synthetic substance, though exhibiting similar colour reactions to aneurin, is not identical with it; on oxidation with potassium ferricyanide it gives a substance non-fluorescent in daylight, but blue fluorescent in ultra-violet light. The difference in fluorescence between thiochrome and synthetic thiazpurines suggests that the former contains a different ring system. Accordingly, the possibility that the formula of Makino and Imai might represent the vitamin has been explored by synthetic methods. These experiments are not yet complete, but a compound similar in structure to (II) has been prepared, which on oxidation with potassium ferricyanide yields a substance exhibiting an intense blue fluorescence comparable with that of thiochrome. We are thus of the opinion that aneurin has a structure of type (II).

Our results afford additional evidence in support of the formula (II: where $R_1 = CH_3$; $R_2 = H$) advanced by Williams as a result of his brilliant investigations. Final proof of the structure must rest with the complete synthesis of the vitamin itself.

A Radioactive Isotope of Iron

IT was shown by Fermi and co-workers[1] that the activity induced in iron by neutron bombardment is due to an isotope of manganese. The isolation of an active iron isotope has not been reported. By means of the sensitive tube counter outfit[2] in this institute, it was found that active iron can be isolated from cobalt which has been irradiated with neutrons, whereas irradiated iron after removal of manganese was found to be inactive. Experiments were carried out with cobalt as metal, as oxide and as carbonate.

After activation, the substance was dissolved in nitric acid and a trace of ferric salt added to the solution. Iron was precipitated from acid solution by means of ammonium acetate, the hydroxide then dissolved again and precipitated once more in the same way, and finally the same process was repeated a third time. The final product (Fe_2O_3) showed an activity decaying with a period of very nearly 72 hours. As only a single cobalt isotope is present in detectable amounts, it can be deduced that this activity must be due to the isotope $^{59}_{26}$Fe. This result is in very good accordance with recent investigations on the isotopic constitution of iron[3], which have shown that the isotopes $^{57}_{26}$Fe and $^{58}_{26}$Fe are stable, being present in amounts of 2·8 and 0·5 per cent of the element. These data also explain why it has been impossible to detect the formation of an active iron isotope by irradiation of iron itself.

Attempts to isolate active zinc from irradiated gallium and active chromium from irradiated manganese gave negative results. The experimental method, however, only allows detection of active products with fairly long periods.

Determination of van der Waals Forces

THE quantum theory, unlike classical theory, predicts a finite effective collision area for impact between gas atoms attracting with a mutual potential energy falling off more rapidly with distance than the inverse cube. It has been pointed out by Massey and Mohr[1] that this makes possible a new experimental method for investigating the magnitudes and nature of these interatomic forces, namely, by direct observation of free paths by molecular ray methods using sufficiently high resolving power. Further, they have given a formula for the effective collision area for any inverse power law of force, from which the results of such experiments could be interpreted.

Since then, Rosin and Rabi[2] have carried out experiments under the required conditions for collisions of rare gas atoms with alkali atoms. The values of the van der Waals energy constant C (such that the van der Waals potential energy of interaction of two atoms at distance r apart is $-C/r^6$) for alkali – rare gas interaction, derived from their results, are given in columns *a* of Table I. (In obtaining these results correction has been made for the random direction of motion of the scattering gas atoms, but not for the Maxwellian distribution of velocities.)

Table I

Values of $C \times 10^{60}$ (erg.cm.^{6}).

	He		Ne		A	
	a	*b*	*a*	*b*	*a*	*b*
Li	14 4	17	18·7	32	188	125
Na	17 8	(26)	40 4	(51)	192	(200)
K	31·7	35	50 5	68	356	260
Rb	25·4	(40)	49 0	(77)	249	(290)
Cs	29·5	44	56·7	87	235	325

These results are of special interest because they may be compared with values of C derived from the polarisabilities of the atoms by a formula due to Hellmann[3]. The polarisabilities of lithium, potassium and cæsium have been measured directly by molecular ray methods by Scheffers and Stark[4] and those of the rare gas atoms may be deduced from measurements of their refractivities[5]. Substituting these values in Hellmann's formula, we derive the values of the constant C given in columns *b* of Table I. The bracketed values have been derived by interpolation, as the polarisabilities of sodium and rubidium have not yet been determined.

It will be seen that the agreement of the two sets of values of C is quite good and suggests that the free path method will prove very convenient for the determination of van der Waals forces. Further experiments in this direction, particularly on mutual collisions between rare gas atoms, would therefore be most valuable. It might be mentioned in conclusion that the scope of the free path method is much wider than that of the older methods depending on gas viscosity and diffusion phenomena.

We would like to express our thanks to Miss R. Sullivan for assistance in some of the numerical calculations.

Bursts of Cosmic Radiation

BURSTS of cosmic radiation were observed in an ionisation vessel 14 cm. diameter and 27 cm. high, filled with carbon dioxide at 10 atmospheres pressure, and completely surrounded by 10 cm. of lead. The sizes of the bursts were estimated as ranging between 35 and 1,800 rays, while the average frequency was 0·88 per hour, with a maximum of four bursts occurring in any one hour.

The magnitude distribution of the bursts in a series of 2,640 observation hours could be represented by the expression

$$B = \frac{8{\cdot}3 \times 10^5}{R_2^{5/3} - R_1^{5/3}}$$

where B=number of bursts (per 2,640 hours) containing between R_1 and R_2 rays ($R_1 < R_2$).

This is of similar form to that suggested by C. G. and D. D. Montgomery to summarise the cascade theory of bursts[1].

The average rates of burst production for various barometric pressure groups were :

Barometer	Bursts/Hour
685–695 mm.	0·911 ± 0·019
695–700 mm.	0 840 ± 0·016
700–710 mm.	0·811 ± 0·019

The barometer effect thus amounts to approximately −0·75 per cent per mm., or about three times as great as that observed here for the bulk of the radiation.

The frequencies with which 0, 1, 2, 3, or 4 bursts respectively occurred per unit period of 57 minutes could be represented by the successive terms of the expansion of the binomial $(q+p)^n$. The values of q and p were found to depend upon the barometric pressure as shown in the following table :

Barometer	n	q	p	P	N
085–695 mm.	4	0·211	0·789	0·32	934
695–700 mm	4	0 205	0·795	0 58	1251
700–710 mm.	4	0·197	0·803	0·32	904

P = the probability that the deviations between the observed and calculated values of the frequency could be caused by random sampling variations (χ^2-test).
N = total number of 57 minute periods of observation.

These results would be explained if the burst-producing radiation falling on the apparatus in the unit time of 57 minutes comprised only a few rays, namely, $n=4$, each of which had a relatively high probability, q, of generating a burst. The assumption that the burst-producing radiation falling on the apparatus is composed of a large number of rays, each with a very small probability of producing a burst, would require that the distribution of the above mentioned frequencies be of the Poisson rather than the binomial type, and this was not supported by the observations.

An increase of barometric pressure brings about a decrease of q with n remaining constant, and this is in line with Swann's hypothesis[2].

Are Hymenoptera Tetraploid ?

A RECENT communication[1] has suggested that among Hymenoptera Symphyta males may be diploid, females tetraploid. It was further suggested that this characteristic might help to explain the phenomena of pre-conjugation as seen in *Apis* and *Cynips kollari*.

More light on the problem may be obtained by taking into consideration available genetic data. If the queen bee is a true tetraploid, one heterozygous for a given recessive factor might be designated *AAaa* and would be expected to produce impaternate diploid drones, an excessive number of which would show the dominant character (the exact ratio of dominants to recessives would rest upon the peculiarities of tetrad or octad formation). However, if the queen bee is diploid and heterozygous for a recessive factor, she would be designated *Aa* and would be expected to produce impaternate haploid drones, equal numbers of which would show the dominant or the recessive character.

Dzierzon, in 1854 (eleven years before Mendel's paper), stated that male offspring from a hybrid queen bee resembled one or the other parental race, the two types appearing in equal numbers. Newell[2] reports that hybrid queens resulting from crosses of yellow Italian and non-yellow Carniolan are themselves yellow and indistinguishable from the Italian parental stock, but "produce both Italian and Carniolan drones, produce them in equal numbers, and do not produce any other kind". A clearer demonstration of this genetic segregation is given by Michailoff[3]. A black-eyed bee, the mother of which was known to have produced white-eyed drones, herself produced a total of 811 white-eyed drones and 806 black-eyed. A black-eyed daughter of this queen, mated to a white-eyed drone, produced 191 white-eyed, 191 black-eyed females and 8 white-eyed, 11 black-eyed drones.

The same method of inheritance has been amply demonstrated by Whiting and his associates in the braconid, *Habrobracon*, for more than 100 mutant genes. Here females show 20 gonial chromosomes, males 10, and the possibility of a diploid–tetraploid condition is made improbable by the presence of one very small chromosome in the male, two in the female, as shown by Torvik-Greb[4] and verified by me. Moreover, recessive mutations in this species have so often been found in but a single male of a fraternity as to indicate that such mutations occurred shortly before maturation of the egg and were made visible by reason of the haploid condition of the offspring.

Also of interest in connexion with this problem is the fact that diploid males, which are occasionally produced in *Habrobracon* from fertilised eggs, show no synapsis of homologues during spermatogenesis and, behaving like haploid males, exhibit an abortive reduction division, resulting in diploid sperm.

Impaternate females likewise may appear in *Habrobracon*; these are diploid, and produce normal haploid sons. Recent cytological work indicates that these females come from unfertilised tetraploid eggs, and by inference, from tetraploid patches in the ovaries of their mothers. If the thelytokous mothers are heterozygous for any recessive factor, the impaternate daughters appear in the ratio of 3 dominants to 1 recessive[5], thus fitting the expectation for diploid progeny from tetraploid gonads.

Thus, although tetraploidy may be a characteristic of lower Hymenoptera, it is unlikely that this condition is normal among representative species of Apocrita. In all cases, genetic evidence would be desirable to back up the cytological findings, since by this means tetraploidy is readily demonstrable.

Bones of a Whale from the Wieringermeer, Zuider Zee

IN 1935, the hind part of a skull, two lower jaws and other bones of a juvenile whale were found in the soil of the Wieringermeer, a reclaimed part of the Zuider Zee. Dr. van Deinse and I came to the conclusion that these bones must have belonged to a young specimen of *Rhachianectes glaucus*. Close comparison of the bones with a skeleton of *R. glaucus* in the British Museum (Natural History) proved that our conclusion was a correct one. Mr. M. A. C. Hinton and Mr. F. C. Fraser are also convinced that our identification is right.

Nearly as interesting, however, is the fact that there are earlier records of this whale in Europe which seem to have been overlooked until now. As a matter of fact, the name *Rhachianectes glaucus* auct. must be changed to *Eschrichtius gibbosus* (Erxl.). Van Deinse and I propose to publish a detailed paper with full synonymy in the journal *Temminckia* in the beginning of 1937.

Immunological Detection of the *Y*-Chromosome in *Drosophila melanogaster*

THE general aim of this line of research is to detect hereditary substances in man and animals by means of immunological methods. We began with experiments on the *Y*-chromosome.

An intensely inbred stock of *Drosophila melanogaster* (Florida) was used. Rabbits were immunised, some by means of a gruel extract obtained from crushed male flies of this stock, and some by means of a similar extract obtained from the virgin females. Serum from the first group of rabbits was adsorbed by means of a gruel obtained from crushed virgin females; serum from the second group was similarly adsorbed by males. In both sera the complement fixation reaction was made by using, as antigens, extracts of gruel of both males and females.

The results are presented in Table I:

TABLE I.*

Material for immunisation	Material for adsorption	Results with ♂♂ antigen (number of experiments)						Results with ♀♀ antigen (number of experiments)					
		++++	+++	++	+	±	−	++++	+++	++	+	±	−
♂♂	♀♀	15	34	3	0	0	0	0	1	13	12	8	18
♀♀	♂♂	0	7	11	12	4	8	2	7	10	11	4	8

* The number of plusses indicates the degree of positive result of the complement fixation reaction, that is, of the absence of hæmolysis.

As evident from this table, the results are not free from defects, chief of which seems to be insufficient adsorption. Apparently the individual characteristics of the rabbits are also of importance, particularly in view of a certain percentage of comparatively weak positive reactions in the series of experiments in which the immunisation was made by means of male extract and the adsorption by means of female gruel, the male extract being used as an antigen.

In view of the possibility that the positive results of this latter series might be considered as due to antibodies formed not against the *Y*-chromosome but against products specific for the male plasm, another series of experiments was undertaken. Serum, derived by immunisation by means of *Drosophila* male extract and adsorbed by means of females of the same stock was, in addition, adsorbed by means of females of the type *XXY* (double adsorption being necessary because the latter females, taken from another stock, evidently differed genotypically from the first line).

The results of this series of experiments are presented in Table II:

TABLE II.

Material for immunisation	Material for adsorption	Results with antigen (number of experiments)						Results with antigen (number of experiments)					
		++++	+++	++	+	±	−	++++	+++	++	+	±	−
♂♂	♀♀ *XX* and ♀♀ *XXY*	0	0	2	2	3	2	0	0	0	0	8	6

Further experiments are in progress. Details as to technique and a detailed report on the results will be communicated elsewhere.

Projection Method for Demonstration of Chromosomes *in situ*

THE demonstration of chromosome preparations has suffered from two serious difficulties in the past. First, the solid form of the object has to be reconstructed from images at different focuses, and it is impossible to be sure that an inexperienced observer has been able to do this. Secondly, chromosome behaviour in general has to be reconstructed from the observation of a great many cells, and their separate demonstration to one student, let alone a large number, is out of the question.

In order to overcome these difficulties (for the summer course of this Institution) we have experimented with the projection of images of the chromosomes on a screen, such as is commonly used for lower magnifications. We find that with a 10 ampère arc lamp, a strong condenser, and a water-ammonia heat-absorbing tank, a sufficient beam of light can be passed through the horizontal microscope (with a ×90 oil immersion apochromatic objective, N.A. 1·3, and a ×5 compensating eyepiece) to give a bright image magnified 5,000 diameters on a screen four feet in diameter and at a distance from the microscope of nine feet. The beam of light between the condenser and the microscope is enclosed to prevent glare. We find that a plain white screen is more satisfactory for our purposes than ground glass, opal glass, silvered or beaded screens. The microscope can be turned on a swivel, and the demonstration interrupted to show ordinary lantern slides.

This apparatus gives equally satisfactory results with well-differentiated hæmatoxylin and gentian-violet staining, with sections of root-tips and with smears of testes and pollen mother-cells. The form and internal structure of the chromosomes—their coiling and chiasmata—and the positions of such bodies as chromomeres and centromeres, 2000 A. in diameter, can be shown throughout the nucleus at focuses varying in depth 20–30 μ. They can be seen by ten or fifteen persons at once with our present experimental apparatus.

The use of this method should enable students to understand chromosomes in a real, and not merely a verbal sense. The apparatus can be made from everyday laboratory equipment and could, we believe, be installed with advantage wherever this subject is taught.

An Early Magdalenian 'Raclette' Industry in the Lower Thames Valley

IN 1930, Dr. A. Cheynier described a newly-discovered industry of Early Magdalenian age, located at Badegoule in the valley of the Vézère, characterised by a large number of end- and side-scrapers made on flakes and showing vertical edge-trimming. He termed these specimens "raclettes"[1]. Mr. A. S. Barnes, who has made a special study of the Upper Palæolithic phases of the Dordogne, refers to this culture in a paper on the Magdalenian period of France, in which he records the close similarity between the edge-trimming on these 'raclettes' and on eoliths[2].

I have lately found, in Stone Court Valley, a 'floor' on the surface of the Lower Flood Plain gravel situated at the base of the Sunk Channel and overlain by an accumulation of alluvial beds and hill-wash. The Sunk Channel was cut in Late Pleistocene times through the gravels of the Upper Flood Plain, which are here overlain by some 10 feet of glacial material. The Stone Court Valley industry is similar to that described by Dr. Cheynier and consists of quantities of 'raclettes', a few carinated scrapers, points with a small notch on each side of the butt (lames à étranglement basilaire), hand-adzes, cores and plain flakes.

Mr. Barnes had already remarked that the retouches upon the Badegoule 'raclettes' recall on a small scale the high-angle chipping on eoliths ; but one of the most interesting features of the Stone Court Valley find is the recrudescence among the other artefacts of specimens analogous, both in sizes and forms, to the Harrisonian eoliths of the Kent Plateau.

The results of this investigation, which I am conducting through the generosity of the trustees of the Percy Sladen Memorial Fund and the kind permission of the management of the Associated Portland Cement Manufacturers, will be published in detail upon its completion.

Scientific Workers and War

THE article on "War, Science and Citizenship" in NATURE of May 9, and the letter on "Scientific Workers and War" published in the following week have expressed views no doubt widely held among readers of NATURE. Neither, however, gives any adequate suggestion as to how those scientific workers who hold such views can make them effective. Any steps depending on collective action through existing scientific organizations are obviously impracticable at the moment, for on the question of war, as on any other question of public policy, there are as wide differences of opinion among scientists as among the rest of the population. No existing organization of scientists, therefore, could at present make any pronouncement, apart from a purely platitudinous one, without serious loss of membership and of effectiveness in other directions.

On the other hand, an individual scientific worker who "first considers what ought to be done and then uses his influence to see that it is done" is acting simply as a private citizen and can do little to achieve that common action of scientists which is desired.

It seems to us, therefore, that the first requisite for any effective action along the lines indicated is the existence of an *ad hoc* organization of those scientific workers whose outlooks are sufficiently akin for an effective common policy to be possible. A policy arrived at by such an organization would not profess to be that of all scientific workers, but would doubtless carry great weight both among their colleagues and among many of the general public who are looking for a new lead. Furthermore, it might well result in existing scientific organizations, with their wider basis of membership, taking some kind of action. At the very least, it would call for a new standard of discussion among those who would oppose it.

A further difficulty must be faced. "To ally ourselves boldly with constructive political forces" as suggested, is not without its dangers. Opinions differ as to which political forces are the constructive ones. On matters where feelings run so high, any decisive action or expression of opinion is bound to cause offence in some quarters, and the offence is bound to be the greater the more original or effective such actions or opinions may be. Owing to their highly specialized training, many scientific workers have even more to fear than most people from the hostility of those who control their means of earning a livelihood. In these very questions to which we believe, with you, that professional scientists can make a distinctive contribution of real value to the community, we believe also that many of them—even in the remaining democratic countries—are kept silent by the certainty that an open expression of their opinions would seriously affect their careers or even bring them to a sudden end. This would certainly apply, for example, in many places to those holding some of the views mentioned in the Cambridge letter. It is with such considerations in mind that there has arisen among the staff and research workers of this University a group whose aim is to investigate the root causes of war and to find means of avoiding it. Isolated groups are, however, of little greater effect than isolated individuals, and we should welcome contacts with similar groups elsewhere in the hope of being able to arrive at a common programme.

Photo-Reduction of Fluorescent Substances by Ferrous Ions

DR. K. WEBER[1] has recently published a note on experiments which he connects with the results published previously by me[2]. There is, however, not much relation between his experiments and my investigations, as may be clear from the following remarks. Dr. Weber seems to be unaware of the fact that by the method which I described it is only possible to reduce fluorescent substances, and then only when they are in a suitable state to exhibit fluorescence. Indeed, his own failure to reduce dyestuffs such as neutral red and Nile blue, which he has reported recently[3], can be attributed mainly to the fact that these dyestuffs are non-fluorescent in aqueous solution.

It has been shown previously that, in principle, every fluorescent substance can be reduced by the influence of light in the presence of suitable reducing substances, for example, Fe^{++} ions, SO_3^{--} ions[4], HS^- ions[5], reversibly or irreversibly. Dyestuffs can always be easily reduced when they are fluorescent in aqueous solution, and Dr. Weber did not fail to confirm this. The reason simply is that the photo-reduction is identical with the elementary process of quenching of fluorescence. The dyestuff molecule in the excited state (F^*) which possesses an unoccupied electronic level (due to the excitation of one electron to a higher level) can take up an electron from a reducing (quenching) substance (into this level) according to the process :

$$F^* + Fe^{++} \rightarrow F^- + Fe^{+++};\quad F^- + H^+ \rightarrow FH \text{ (reduced dyestuff).}$$

In this way the excitation energy in effect increases the electron affinity of the dyestuff molecule (F). When there is no fluorescence, there are no excited dyestuff molecules of an appreciable life-time, and consequently no photo-reduction can take place.

The photo-reduction is not quite so simple in the case of chlorophyll and other fluorescent substances which give non-fluorescent aqueous solutions, and where it is necessary to use a suitable mixture of solvents (for example, aqueous methyl alcohol), in which the ferrous salt is sufficiently soluble and also the dyestuff (chlorophyll) is capable of fluorescence.

Further details are given in a paper[6] which has recently appeared, and an additional paper on the same subject will be published shortly.

Points from Foregoing Letters

To explain the elastic properties of viscid fluid threads, Sir Joseph Larmor imagines their molecules to be shaped like dumb-bells, interacting by forces between their ends, so that when two rows lie in parallel there is a position of equilibrium when the ends are opposite each other, and an elastic reaction comes into play which allows of a large range of reversible extension.

Crystalline pepsin is inactivated at a rate inversely proportional to the fifth power of the hydrogen ion concentration, between pH 6·2 and 6·45. This behaviour, Dr. J. Steinhardt considers, suggests the presence of an unstable pepsin ion, formed by the dissociation of five acidic groups with dissociation constants near $1{\cdot}7 \times 10^{-7}$.

From the reaction shown by regenerated tails of tadpoles and pieces of *Euplanaria* with sodium nitroprusside, N. S. R. Maloeuf concludes that the nitroprusside colour test is specific for the oxido-reduction enzyme glutathione, when applied to normal living tissues and when ammonium hydroxide is used as the alkali. Heat must not be applied, since it liberates free —SH radicals from protein, which then give a colour with the nitroprusside and invalidate the test both for glutathione and cystein.

F. Bergel and A. R. Todd discuss the possible structural formulæ of aneurin (vitamin B_1) and its oxidation product, thiochrome. Certain synthetic compounds show a fluorescence similar to that of thiochrome, and their known structure supports the formula suggested by Makino and Imai, and modified by Williams.

The formation of a radioactive isotope of iron by irradiation of cobalt with neutrons is reported by Prof. E. B. Andersen. The new isotope is probably iron of mass 59, and shows an activity decaying with a period of nearly 72 hours.

Dr. H. S. W. Massey and R. A. Buckingham calculate the values of the van der Waals' interatomic constant from observations by Rosin and Rabi on the collision of rare gas atoms (helium, neon and argon) with alkali atoms, observed by the molecular ray method. The authors compare the values with those derived from the polarizabilities of the atoms, and conclude that the free path method will prove convenient for the determination of van der Waals' forces.

An investigation by A. R. Hogg of bursts of cosmic radiation of estimated size 35–1800 rays suggests that the rays responsible for producing these bursts occur relatively infrequently, but that each ray has a fairly high probability of producing a burst. This probability varies with the barometric pressure.

Instances are quoted by B. R. Speicher to show that hybrid queen bees produce equal numbers of impaternate drones with dominant and with recessive characters. Hence he concludes that the impaternate drones in bees and wasps (sub-order Apocrita) are 'haploid', that is, they have the basic number of chromosome number in their nuclei, and are not 'diploid' as recently suggested in the case of male impaternate saw-flies (sub-order Symphyta).

The formation, in rabbits' serum, of 'antibodies' specific for the Y-chromosome of the male fruit-fly, after injection of a gruel of the insects, is indicated by experiments carried out by Dr. S. G. Levit, S. G. Ginsburg, V. S. Kalinin and R. G. Feinberg. An antibody when formed in the serum of living animals after the injection of an 'antigen' (in this case, extract of fruit-flies) 'fixes' the 'complement', a ferment which, in conjunction with an 'amboceptor', hinders the break-up of red blood cells and of bacteria.

A simple arrangement for the direct projection on a screen of microscopic slides showing the internal structure of chromosomes is described by Dr. C. D. Darlington and H. C. Osterstock.

J. P. T. Burchell reports the finding, in Stone Court Valley, of a 'floor' containing stone implements, including 'raclettes', at the base of the Sunk Channel, cut in Late Pleistocene times. The artefacts show features analogous to those observed among the 'eoliths' (earliest stone implements of tertiary age).

Antiquities of the Jumna Valley

AN investigation by Prof. B. Sahni of mounds on the outskirts of the city of Khokra Kot, where their structure has been revealed by ravines cut through by rains, has produced a large number of relics, old bricks, pottery, etc. (*Current Science*, May 1936). A well-defined dark layer exposed in the side of a cliff at three feet below the surface, yielded hundreds of black terra-cotta disks, afterwards identified as moulds for coins. These, as is shown by a Brahmi inscription, must be assigned to the Yaudhiyas and dated at about 100 B.C. Some were found afterwards still to contain coins. The coins are of bronze. On the obverse is a humped bull, looking to the right, with head obliquely pointing to the observer. In front of it is the conventional sign for a tree enclosed within a railing. On the reverse is an elephant, also pointing to the right, in various postures of walking or running, with trunk upraised. In some, the tail is bifurcated. Above is the Brahmi letter *ga* and the *triratna* or *nandipada* symbol. The matrices were either baked over a slow fire of paddy or wheat and barley, or they were packed in them, when the molten metal was poured in. They show impressions of the paddy straw, and charred grains adhere to them in the form of a carbonized crust. A terra-cotta model of a humped bull probably came from the same level. Other relics belong to a distinctly lower, and probably earlier, level. A glazed pot of white paste bears on its inside a clear impression of a finely woven cloth. In this was an ink-like substance, which analysis has shown to consist of carbon (lamp-black) with mineral substances. A shell bead is carved out of the columella of a large gastropod. It is suggested on the ground of the resemblances of these objects in style to antiquities from Mohenjo-daro and Harappa, that there may be in the Jumna valley a tradition of a connexion with the Indus valley civilization, which systematic investigation on this site might confirm.

Antithyrotropic Activity

THE injection of extracts of anterior pituitary causes hyperplasia of the epithelium of the thyroid gland and general symptoms of hyperthyroidism. The effect on the thyroid is not maintained for long, and the symptoms of hyperthyroidism disappear, in spite of the continuance of the injections. Collip and Anderson showed that this disappearance of the effects is due to the appearance of inhibitory antithyrotropic substances in the blood. Rowlands and Parkes (*Proc. Roy. Soc.*, B, 120, 114; 1936) have studied the properties of this antihormone. Inhibition of the effect of thyrotropic extract on the weight of the thyroid of the immature guinea pig was used as a test of antithyrotropic activity, and a method of assay is described. Normal blood has no action. If thyrotropic extract is injected daily into rabbits, antithyrotropic activity begins to appear after four weeks and reaches a maximum in ten weeks. The results described are in complete agreement with the antihormone theory of Collip and his co-workers. It would be difficult to over-estimate the biological importance of this theory.

Northern Phytoplankton and its Production

DR. E. STUMANN NIELSEN has investigated the general plankton production conditions in the Faroe, Icelandic and East Greenlandic waters proper as well as dealing, although in less detail, with the whole of the northern region of the Gulf Stream and the bordering colder regions (*Meddelelser fra Kommissionen for Danmarks Fiskeri og Havundersøgelser*. Serie: Plankton. 3, No. 1; 1935). He gives the results during 1932–34, made chiefly with the Danish research ship *Dana*. All the plankton work was done in close co-operation with the hydrographic observations, and in 1934 the transparency of the water was also registered. The phytoplankton production is one of the most important links in the chain of factors leading to the production of great fish populations. On it depend the fisheries of all our seas either directly or indirectly. The conditions of production are of a very diverse character in the different seas around Iceland and the Faroe Islands, the factors that are of importance do not act in the same way everywhere, and it is only when they act together as a harmonious whole that the possibilities of production are optimal. Light and the quantity of nutritive salts are of supreme importance in restricting the plankton production in northern waters, but there depend many other factors which partly work into one another, such as stabilisation of the surface layers and the transparency of the water (including amount of detritus present); temperature and salinity having as a rule only a regulating effect. More exact studies into vertical movements of the volumes of water in the sea are advocated and also systematic investigation regarding the transparency of the sea throughout the year, together with detailed inquiries into the relation between the areas with large production of phytoplankton and those with great fish populations.

Researches on the Sucking Lice

THERE has recently come to hand Part 8 of "Contributions towards a Monograph of the Sucking Lice" by Dr. G. F. Ferris, and published by the Stanford University Press, California. This fascicle forms No. 8 of vol. 2, Stanford University Publications, Biological Series, 1935, and completes the monograph concerned. It deals especially with the lice of man and certain other primates. The author arrives at the conclusion that the genus *Pediculus* contains but three species. The question, so often debated, as to what constitutes a species is of particular interest in connexion with this genus, and the author defines his attitude as regards the problem as definitely as possible. Of the three species recognized, *P. humanus* L. is adopted as the name for the whole assemblage of Pediculi found on the races of man. It seems clear that it can also establish itself upon other primates which have been in contact with man. The validity of the author's conclusions remains to be tested by experimental work upon the various forms that are known to occur. The second species, *P. mjöbergi* Ferris, infests monkeys of the family Cebidæ, and *P. schäffi* Fahrenholz occurs on the chimpanzee. Of the genus *Phthirus*, in addition to *P. pubis* (L.), the existence of a second species, *P. gorillæ* Ewing, is doubtful, and adults are, as yet, undescribed. The fascicle concludes with an appendix relating to Anoplura dealt with in the earlier parts of the monograph, and an index.

Inhibitors of Tobacco Mosaic Virus

SEVERAL viruses produce local lesions upon the inoculated leaves of certain host plants, and this capacity has been used to test the effects of various inhibiting substances. It has not, however, always been possible to determine whether the inhibitor was acting upon the virus or the host, but Dr. J. Caldwell has evolved an interesting technique to separate these effects ("Factors affecting the Formation of Local Lesions by Tobacco Mosaic Virus", *Proc. Roy. Soc.*, B, **119**, 493–507, March 1936). The earlier part of the paper shows that if the inhibitor acts upon the virus, its effect should increase with decreasing virus concentration, and the reverse effect would indicate inhibitory action upon the host. Experiments with normal sera of horse and rabbit, with trypsin, and with silver nitrate, indicate that all these inhibitors act upon the virus. The mode of action is not yet quite clear, but should form a fascinating subject for future study.

Unity of Force and Matter

THE Masaryk Academy of Work has just published a thesis by Dr. J. Bašta entitled, "L'unité de la force et l'unité de la matière dans la conception physique uniforme du monde", in which the author sets out to show that, mathematically and physically, all matter is composed of what he terms 'proto-atoms'. Experiments are cited to indicate the possibility of reducing the various causes of pressure and acceleration, for example, cohesion, adhesion, chemical affinity, adsorption, vapour pressure, osmotic pressure, gravity, magnetic and electrical attraction and repulsion, etc., to a single force. This force is the cause of strain in static states and of acceleration under dynamic conditions. It is supposed that this simple force is the attraction of the smallest elementary particles of matter (proto-atoms). The range of action of these bodies is limited by the amplitude of their vibrations. The attraction is transmitted only by contact of one particle with its neighbour. All action at a distance is excluded. The primary sources of this elementary attraction are the proto-atoms. Atoms of the chemical elements and also the ultimate particles of cosmic ether represent different complexes of these ultimately simple proto-atoms which, it is postulated, are only able to exercise an influence on primary matter in their own material system or on other systems by their residual lines of force.

Oceanography and Meteorology of China Seas

Koninklijk Nederlandsch Meteorologisch Instituut publication No. 115, entitled "Oceanographic and Meteorological Observations in the China Seas and in the Western part of the North Pacific Ocean", is a large atlas in which are set out cartographically the extensive observations collected during many years by Dutch and other ships in East Asiatic waters in a similar form to that of the atlases of the Indian Ocean (Publication No. 104) and of the Atlantic Ocean (No. 110). The text is in Dutch, with an English translation, but the names on the maps are in English only. The work is in accordance with the recommendations of the Fourth Pacific Science Congress of 1929 at Batavia for active international co-operation to develop the practical and scientific aspects of oceanography and meteorology, and for this reason more observations from ships of other nationalities—especially those of Great Britain, the United States, France and Germany—have been used than in the case of the similar earlier Dutch publications. The result is an impressive mass of marine statistics set out in great detail and with admirable clearness, on charts roughly 18 in. × 18 in. It is a bulky publication, which when open occupies a space of 3 feet 6 inches by nearly 2 feet, but by adopting a large size for the charts excessively small lettering has been avoided. For the General Current Circulation 'one degree squares' are used. Each of these contains an arrow showing the average observed resultant current, and figures alongside giving the average speed in nautical miles per day and the number of observations, while the stability of the circulation is shown by the length and thickness of the arrow. Each month is dealt with separately; the information just described is shown on the left hand page at an opening, while on the right hand page the current roses for the same month are given on 'squares' of rather larger size—generally 5° of longitude by 3° of latitude. These roses follow a well-known standard form, the percentage frequency of a given direction of current being shown by a suitable length of line on the scale 1 mm. = 2 per cent, and various ranges of speed are represented by various thicknesses and shadings of line. On the same system of 'squares' the monthly data for the ordinary meteorological elements, wind, fog, precipitation, pressure, air and sea surface temperature are set out, and also the tracks of the more important temperate depressions (here designated continental depressions) and typhoons.

Iron Wire and Nerves

IN the study of complex problems, the construction of a simplified model may serve as an aid to comprehension. It is now eighteen years since R. S. Lillie first directed attention to the similarity between the properties of iron wire immersed in nitric acid and those of living nerves. During these years the phenomenon has been more closely studied, and many more points of similarity have been discovered. A review of the present situation has recently been published (*Biol. Rev.*, **11**, 181; 1936). When the iron wire is placed in nitric acid it is quickly covered with a film of oxide which protects it and makes it 'passive'. If this film is broken, the damaged area becomes anodal and local currents flow which break down a new area of the film, and this in turn 'stimulates' another area and an 'impulse' passes along the wire. When the impulse has passed, the damage is quickly repaired. The model resembles nerve in the fact that it can be stimulated by electric currents, and the laws governing the conditions necessary for excitation are similar. The 'chronaxie' of a certain model was about the same as that of heart muscle. After stimulation, the model shows an absolute refractory period followed by a relative refractory period. The temperature coefficients of the two processes are about the same. If the wire is enclosed in a tube the velocity of transmission is diminished. This is compared with the slow transmission in small nerve fibres. If a wire is enclosed in a series of short tubes, the impulse can jump straight from one node to the next and the impulse passes quicker than normally. This is compared with the nodes on the myelin sheath of certain quickly-conducting nerves. Under certain conditions, models may show rhythmical activity.

Centenary Celebrations of the University of London

THE hundredth anniversary of the University of London was celebrated during the week June 29–July 3 with a full programme of functions. The proceedings were inaugurated at an afternoon reception on Monday, June 29, in the Great Hall of the University at South Kensington. Here nearly two hundred representatives of universities and learned societies in every corner of the globe assembled to present addresses of congratulation and goodwill. The Chancellor, Lord Athlone, in welcoming the delegates, said that this great convention was a healthy reminder that learning recognized no national frontiers, that the whole band of great teachers, the whole band of eager students, were truly citizens of the wide world, and their influence for good was incalculable and illimitable. Honorary degrees were conferred on the following distinguished men, who were presented by the Public Orator: The Archbishop of Westminster, Dr. J. W. Mackail, Sir Charles Peers, Prof. G. M. Trevelyan, Mr. H. G. Wells, Senor Don Ramon Perez de Ayala (Doctors of Literature); Mr. S. A. Courtauld, Mr. P. M. Evans, Sir Joseph Larmor, Sir George Newman, Lord Snell, Lord Wright (Doctors of Law); Dr. R. Vaughan Williams (Doctor of Music); and Sir William Bragg and Prof. Max Planck (Doctors of Science). Degrees were also conferred *in absentia* on Dr. Emile Legouis (Doctor of Literature); Mr. Justice Cardozo (Doctor of Laws); Prof. Albert Einstein and Prof. Johan Hjort (Doctors of Science).

In the evening of the same day, a dinner was held at Grosvenor House. The Chancellor, who presided, read a message from His Majesty the King, Visitor of the University, conveying his sincere congratulations to the University on the occasion of its centenary, and alluding to the progress of the new buildings at Bloomsbury as marking the beginning of a new era as well as a new century in the life of the University. Sir Thomas Inskip, in proposing the toast of "The University", said that within the space of a hundred years the University had attained such a position that it was able in everything but antiquity and beauty of situation to challenge the supremacy of the two great Universities of Oxford and Cambridge, and had fully justified the foresight of those who founded it. Time would make it as venerable as its rivals, and the generosity of public and private benefactors would soon enable the University to have buildings as beautiful and as well placed as any in the land.

The Chancellor, in reply, commented on the happy spirit of co-operation and goodwill which to-day existed between the learned institutions of the world. The exchange of teachers and students and ideas was of the utmost significance, and the Universities of the world might well claim that they were making a contribution of high value and importance in the promotion of peace and understanding. He stressed also the importance of unity, though not necessarily uniformity, within the University itself, and remarked on the analogy which the constitution of the University, with its federation of semi-autonomous Schools, presented to the British Empire. The one was no less real than the other. "The respective spheres of University and College", he said, "are clearly defined in black and white but no written statute is of any avail apart from that spirit of goodwill, that desire to pull together, which is characteristic of London University". The toast of "The Guests" was proposed by the Vice-Chancellor, Mr. H. L. Eason, who said: "This great gathering is a token that the ideal that should underlie all Universities is not forgotten, namely, that academic learning should have no boundaries of space, nationality, religion or politics. Without this spirit, learning would have perished in the Middle Ages, and there never was a period in the world's history when the maintenance of complete academic freedom of thought was more urgently needed than to-day". Prof. Louis Cazamian, of the University of Paris, Mr. G. H. Wilson, vice-chancellor of the University of Cambridge, Prof. L. P. Eisenhart, of Princeton University and Sir James Barrett, Chancellor of the University of Melbourne, responded, and congratulated the University on the distinguished record of its first hundred years.

Tuesday, June 30, was devoted mainly to functions at the various Colleges, while in the evening the Worshipful Company of Drapers, old and generous friends of the University, gave a ball at the Drapers' Hall.

On Wednesday, July 1, the University's friendly relations with the City of London were once more demonstrated and reaffirmed. To the special service of thanksgiving at St. Paul's Cathedral came a vast congregation of members and friends of the University. The citizens of London gazed upon a striking and colourful scene as the processions in academic costume wound up Ludgate Hill. First the professors and readers entered the Cathedral. Then came the Lord Mayor, the Sheriffs and Corporation; and finally the Chancellor's procession, consisting of the delegates from sister universities and learned bodies, honorary graduates, the Court and Senate and the Chancellor. The service, which was broadcast, was impressive in its simplicity. The Archbishop of Canterbury, in an eloquent sermon, paid tribute to the high ideal which had animated the founders of the University one hundred years ago and which was still incorporated in the Statutes, "to hold forth to all classes and denominations without any distinction whatsoever an encouragement for pursuing a regular and liberal course of education". This ideal was now accepted as a commonplace of public policy, but in those days great courage was needed to assert it. The University had been a pioneer of the movement which had given universities to most of our large cities, and though unlike its younger sisters it had not been able, by reason of the vastness of London, to make such an impact on the life of the city, the presence of an institution which not only prepared students for profitable and useful careers but which also fostered the things of the mind and the spirit, the pursuit of knowledge and truth for their own sake, was of incalculable benefit to London. Throughout its development the University had lacked one thing—a body, so to speak, in which its soul might find a fitting home. This was now at last to be remedied, and at Bloomsbury there was arising a great building wherein for the first time the length and breadth and depth and height of the ideals for which the University stood would find a visible, noble, enduring embodiment and witness—a reminder to London that it had its own University in its midst.

After the service, the Lord Mayor and Corporation gave a luncheon in Guildhall. Lord Halifax, speaking as Chancellor of the University of Oxford, said that one of the greatest achievements of the nineteenth century was the assertion of the principle of an extended university education. This had inevitably given rise to a tendency to consider that the progress of the human race was automatic, provided that education could be sufficiently widely diffused. It was, however, being increasingly realized in these days that much knowledge might be a dangerous and destructive thing unless it was directed by something greater than itself. One had only to think of man's discovery of aeroplanes, of chemical laws and products and even of the internal combustion engine, to realize how dangerous they could be, unless guided and inspired by that which was greater than themselves—wisdom. Civilization must depend on training men to become masters rather than victims of their own inventions. No greater aim could be set before a university, and they could wish no better thing for London's university than that for the next critical century of its history it might continue to inculcate those principles to which in the past hundred years it had been so faithful.

The Chancellor, in reply, said that the first and perhaps the most difficult stage of the University's history was now past, and they might recall, with justifiable elation, the apprehension and dismay with which at the outset the project was greeted. All that the University had striven and was striving for would be consolidated in its new home, and there the University would pursue its course, going quietly and steadily forward; and when the next hundred years had passed there would be found the same spirit, the same high ideals, which animated the University of London to-day.

Lord Macmillan, chairman of the University Court, who proposed the toast of "The Lord Mayor and Corporation", referred to the friendly relationship between 'town and gown' which had always existed in London, and recalled episodes separated in time by more than a hundred years in which the City Corporation had shown its great interest in the cause of university education in London. The University, like the City, was engaged in commerce —not of commodities but of ideas—a commerce which knew no quotas, no embargoes, but where universal free trade existed. The best means for bringing about in the distraught world a renewal of friendship, mutual confidence and well-being, was by the promotion of those common bonds which scholarship and learning alone could furnish. The Lord Mayor, responding, said that the Corporation of London had always identified itself with the cause of education and had ever striven for that freedom of thought and action, in the wise and appreciative use of which the finest achievements of the human mind had become available for the benefit of mankind.

In the evening, His Majesty's Government held a reception at Lancaster House, where the guests were received by the Lord President of the Council and Miss MacDonald.

The proceedings were brought to a conclusion on Friday, July 3, with a brilliant reception given by the London County Council, the hospitality of which once more bore witness to the generosity and goodwill which characterizes its relationship with the University.

Throughout the week, hospitality was freely extended to the delegates by the Colleges and Schools of the University in the form of luncheons, garden parties, dinners and evening receptions, and all offered facilities for the visitors to see something of their work and activities.

A memorable occasion was thus worthily celebrated. The University, on the threshold of a new phase of its existence, may well be satisfied with the demonstrations of loyalty and friendship which the completion of its first hundred years has evoked, not only from those within its bounds but also from all those far and near who come into contact with its widespread activities.

The National Physical Laboratory

ANNUAL INSPECTION

ON July 1, the annual inspection of the work in progress at the National Physical Laboratory was made by the General Board and also by a large number of visitors representative of scientific, academic and commercial institutions throughout the country. The visitors were received in the High Voltage Laboratory by Sir William Bragg, president of the Royal Society and chairman of the Board, the Right Hon. Lord Rayleigh, chairman of the Executive Committee, and Sir Frank Smith, director of the Laboratory. Some three hundred exhibits illustrating the work performed in the eight departments of the Laboratory were on view; a brief summary of some of the more recent or interesting developments is given below.

In the Physics Department, the analogous problems of the transfer of heat from metal pipes and moisture from wet surfaces to a stream of air flowing over them have been investigated, and similar laws are found to hold for the two processes. The effect of inducing turbulence in the air-stream has also been studied. A simple falling plug method for determining the viscosities of liquid refrigerants has been devised. The apparatus is calibrated with liquids of known viscosity, and may easily be adapted to work under pressure and at low temperatures. The investigation of the changes of length of hygroscopic materials with humidity has continued and a demonstration was given of the application of such a material—gold beaters' skin—to the maintenance of constant humidity in a chamber. The thermal conductivity of a variety of materials used in building and refrigerating practice has been measured with the cold face at normal or low temperature. The thermal conductivity of metals at high temperatures is obtained by connecting the specimen in series with a rod of iron of known conductivity and measuring the temperature gradient through the latter.

Work on the application of X-ray methods to industrial problems has continued in the Radiology Division with the object of correlating the physical, electrical and magnetic properties of materials with their lattice structure. In this connexion, the effect of fatigue stresses on the structure of mild steel specimens has received a considerable amount of attention recently. For the checking of 'air-wall' ionization chambers designed to measure radium dosage in röntgen units, a 'free-air' ionization chamber approximately 10 ft. square in cross-section has been constructed and was exhibited. The experiments with this have shown that the results obtained with an 'air-wall' ionization chamber of suitable wall thickness are quite trustworthy. A single-stage electrometer-valve amplifier has been used for the rapid measurement of radium by the γ-ray method. The results obtained with it agree satisfactorily with those given by the standard apparatus.

A considerable amount of test work on sound-absorbing and other building materials has been carried out in the Acoustics Laboratory, and routine testing of the transmission of sound through walls and floors was demonstrated. The methods for the calibration of microphones in absolute measure have recently been extended, and standard instruments were shown, the calibration of which was known over the whole frequency range from 10 to 10,000 cycles per second. The standardizing apparatus and lagged chamber with which these calibrations were obtained were also on view.

In the accurate calibration of thermocouples it is necessary to maintain the furnace at a constant temperature for relatively long periods. A high degree of thermostatic control has been obtained by making the platinum heating element one arm of a Wheatstone's bridge which is arranged to be balanced at any desired resistance—and hence temperature—of this element. In this way it has been found possible to control the temperature at any point in a furnace to 0·01° C. at temperatures in the region of 1,000° C. A very close approach to a true black-body radiator has been realized by introducing a hollow nickel cylinder into a tubular furnace thermostatically controlled as above, and compensating for the axial temperature gradient in the nickel by additional heating elements at its ends.

In modern optical instruments, considerable attention has been paid to the attainment of greater light efficiency, and field brightness tests have assumed greater importance than hitherto. Photo-electric methods have now replaced the ocular methods previously used, and greater precision and rapidity in carrying out these tests have resulted.

The high precision obtained in frequency measurement in the Electrical Standards Division of the Electricity Department by the use of quartz ring and tuning fork oscillators has now been utilized so that the whole of the audio frequency range may be covered in small steps by frequencies which are known to within a few parts in 10^6. An oscillator of multivibrator type is tuned approximately to the frequency required, which must be a submultiple of 1,000, 20,000, 40,000 or 80,000, and is then held in step by an output of one of the above frequencies obtained from the primary standard. In this Division also the use of platinum as a material suitable for standard resistance coils has been investigated. The high temperature coefficient of this material necessitates a very accurate control of the temperature at which the coils are measured, but nevertheless with suitable precautions it has been found that results consistent to about 1 part in a million may be obtained. A very useful method of measuring dielectric properties at very high frequencies has recently been developed. It depends essentially upon the measurement of the width of the resonance curve of a tuned circuit which contains the specimen under test. Measurements over the frequency range 10^4–10^8 cycles per second have been made by this method.

The stroboscope method of frequency control in the Electrotechnics Division has been materially improved during the past year by the elimination of contacts on the standard tuning fork. A valve-maintained fork is now used, the output coil of which is connected to the grid of a thyratron. By this means a charged condenser is made to discharge through the thyratron and the primary of an induction coil once per fork cycle. Special neon lamps connected in the secondary circuit of the induction coil illuminate the stroboscope disc.

In the High Voltage Laboratory researches on the effect of transient voltages on insulation in general are proceeding, and the technique of high-speed cathode ray oscillography has been further improved. The testing of a lightning arrester connected across the end of the new overhead transmission line was demonstrated.

During the past year a new Photometry Building has been erected to accommodate the photometric work and the illumination research of the Electricity Department. In the design and equipment of the building special attention has been paid to the particular requirements of this work. In addition to rooms for routine photometry, preparation and maintenance of substandards, and experimental research, the building contains a wide room 145 feet long for work on all types of projection apparatus. By opening a roller shutter at one end of this room, the range over which this work is carried out can be extended when necessary to nearly 800 feet. Various problems in connexion with glare and its after-effects are being examined in the Division. To enable the results to be applied in practice, a knowledge is required of the rate of expansion of the natural eye-pupil during recovery from exposure to a high brightness. The subject is most conveniently studied by taking a cinematograph film of the eye during recovery, using for this purpose infra-red radiation, which does not affect the phenomenon under investigation.

A photo-electric daylight factor meter has been developed in the Division. The instrument consists in essence of two rectifier photo-cells in circuit with a microammeter. One is placed on the window-sill and receives light from a definite small solid angle of the sky. The other, which is compensated for light obliquity, is placed at the point where the daylight factor is to be measured. There is a variable resistance in parallel with the photo-cell on the window-sill. The mode of operation is to adjust this resistance until the microammeter reading remains the same, when it is connected in succession to the photo-cell resistance combination and to the photo-cell in the room. By means of a calibration curve, the daylight factor is given directly by the values of the resistance.

A photo-electric spectrophotometer, incorporating a thin film potassium photo-cell, has been designed for the rapid determination of the spectral transmission of coloured filters. A method has been devised for checking the linearity of the photo-cell characteristics at any desired wave-length.

In the Radio Department advantage has been taken of the fact that magnetron valves used for generating very short waves may, by the application of sufficiently intense magnetic fields, be made to operate at frequencies at which direct measurements of their input impedance are possible. In this way it has been found that electronic oscillations occur in such a valve near the condition of resonance. A portable direction-finding receiver for operation on wave-lengths between 8 metres and 10 metres was exhibited. The receiving loop is screened inside a solid copper tube and a push-pull input connexion to the first stage of the receiver is used to maintain electrical symmetry. A direct-reading frequency-measuring equipment has recently been constructed in this Department whereby the frequency of any radio oscillations between 1 and 70 megacycles may quickly be determined with an accuracy of 1 part in a million.

With the object of achieving greater stability in the frequency of transmitters, the work on design of condensers and inductances of low temperature coefficient of reactance has continued and a selection of such components was shown. An automatic monitoring system for the control of the frequency of a transmitter by a stabilized master-oscillator has been developed for use with the above. A novel exhibit in this Department was the outcome of co-operation with the Forest Products Research Laboratory. The apparatus was designed to detect the presence of destructive insects in timber, and consists of a sound-proof chest, a sensitive microphone and a high-gain amplifier. The microphone is placed in contact with the specimen of timber in the inner box of the chest, and any faint sounds created by destructive insect activity are received by the microphone and amplified to audible level.

Among the exhibits in the Metrology Department mention should be made of the interference apparatus for precise measurements of the refractive index of air. The method consists in the observation of Brewster's fringes in monochromatic light produced by two tubular invar étalons, one being permanently evacuated and the other containing dry air under the required conditions of test. The latter étalon is then evacuated, and from the change in the fringe system the value of μ-1 may be calculated. Measurements on photographic records of the fringe patterns made with the aid of a microphotometer enable a precision of 0·01 of a fringe interval to be obtained.

The new type of comparator for block gauges is now completed, and offers increased facilities for measuring the larger sizes of gauges to an accuracy of a millionth of an inch. The new pitch measuring machine for tapered screw gauges has also been completed. In addition to these exhibits, a large variety of machines used in the routine testing of engineers' gauges of every description was shown. An automatic pipette for the delivery of small and accurately known quantities of mercury was demonstrated in the Glass Testing Building.

Research in the Engineering Department on the structural changes associated with static and fatigue fracture of metals has been continued throughout the year: the X-ray method of attacking this problem has proved very valuable, since the primary cause of failure is associated with changes of a sub-microscopic nature in the crystalline structure. In connexion with researches in this Department on the wind pressures around buildings, the experiments on isolated models have now been extended so as to determine the effect of neighbouring structures. In order to obtain results which may be applied to structures in built-up areas, a model of the buildings lying in an area about half a mile square immediately to the north of the Thames Embankment has been constructed. This can be accommodated in the 14-ft. wind tunnel, and the actual test model is placed near the middle of this built-up area. Other aerodynamical problems under investigation are the characteristics of air streams loaded with granular matter, and the effect of roughness of pipes on air flow through them.

Wheel impact measurements have been continued throughout the year on a six-wheeled lorry under various types of loading, tyres and road surfaces. The equipment for carrying out similar tests on a private car has just been completed, and an economy in size and power consumption of the recording apparatus has been achieved. Typical records obtained in the course of this investigation were exhibited.

In the section devoted to lubrication research, refined measurements have been made of the change of shape at the crown of the bush when a plain bearing is run to seizure. The beneficial effects of rotation in both directions during the running-in of a bearing have also been demonstrated. The influence of temperature and rate of oscillation on the friction developed in an oscillating bearing is also under investigation, and the characteristics of various oils, in particular the extreme pressure lubricants recently developed, have been studied with the aid of two new machines in which the bearing surfaces are well defined. An investigation into the behaviour of bolted pipe flanges under high-pressure high-temperature steam is being carried out with the view of obtaining leak-proof joints in pipes operating under these conditions.

Among the researches in progress in the Metallurgy Department, that dealing with the alloys of magnesium promises to have important commercial results on account of the lightness combined with strength of some of these alloys. The technique of working such alloys is also being developed. Work on alloy steels for use at high temperatures is being continued, and corrosion tests on specimens exposed to high-pressure steam have been carried out. A method of determining thermal curves at high temperatures *in vacuo* was demonstrated in the high-frequency furnace room. The accessory apparatus made and used in the routine work of this Department was exemplified by a comprehensive display of refractory materials, including articles of sintered alumina and thoria for use at very high temperatures. A potentiometer was also demonstrated by means of which thermal curves of metals and alloys can be plotted automatically on a chronograph. The potentiometer dials are operated by an electric motor which is controlled, through a relay and photo-electric cells, by the light reflected from the galvanometer mirror.

An interesting exhibit in the Aerodynamics Department was an instructional film produced in this Department to show the flow of air around various models. The flow is made visible by producing a succession of hot spots in the air stream by means of spark discharges and observing them by the *Schlieren* method of illumination. The transitory and steady state conditions following the initiation of the air stream were illustrated with several models. By using a high-speed camera, it is possible by this method to analyze changes in the motion which are far too rapid to be seen by the eye.

The high speeds at which modern aircraft now operate have called for aerodynamical surfaces and shapes which offer as little drag as possible. This is not always compatible with the attainment of the requisite mechanical strength in the part concerned—notably in the case of monoplane wings, which need to be thickened at the root in order to be sufficiently strong. Tests have been carried out on such wings in order to determine the best conditions of compromise between drag and strength. The drag on aerofoils at high speeds where compressibility of the air becomes of importance has been measured directly on a balance and indirectly by measurements of the loss of momentum of the air stream at various points behind the model. The latter method is valuable since it may be applied to an actual machine in flight and hence allow of the separation of the scale effect and the compressibility effect in going from the model to the full-scale machine.

At the other end of the scale, the stability of aircraft at low speeds is receiving considerable attention, and the effect of slots and flaps and other landing devices is being studied. A demonstration was given of a model being tested in this way. The model is given a slow rolling motion, and measurements are made to determine whether such motion tends to be checked or accentuated. In order to verify a simple empirical formula which has recently been suggested for predicting flutter speed from the resonance frequency of a wing in still air, various types of wing have been under test in order to determine to what extent a numerical factor in the formula varies with the types of wing generally used.

In the Yarrow Tank of the William Froude Laboratory, experiments were being conducted on a self-propelled model cargo vessel, the rolling of which was measured continuously from an initial angle of heel. The tests are being made to differentiate between various types of keels and their position on the hull, and also to throw light on the effect of factors of design upon the extinction of rolling.

The effect of rate of revolution of twin-screw propellers on their propulsive efficiency has recently been studied. The results show that for any given pair of screws, there is an optimum speed of rotation at which this efficiency is a maximum. In addition to these exhibits, a variety of instruments for making tests on models and full-sized ships was exhibited.

South-Eastern Union of Scientific Societies

ANNUAL CONGRESS AT OXFORD

THE South-Eastern Union of Scientific Societies met for the first time in its history at Oxford on the occasion of its forty-first annual congress on June 30–July 4. Prof. G. D. Hale Carpenter, Hope professor of zoology at the University, occupied the presidential chair. The congress was held under the patronage of the Vice-Chancellor of Oxford, A. D. Lindsay, Master of Balliol College, and the Pro-Vice-Chancellor, the Warden of Wadham, welcomed the members at Rhodes House at its first meeting.

Prof. Hale Carpenter chose as the subject of his address "Charles Darwin and Entomology". The subject was, he said, of peculiar interest at Oxford, for his predecessor in the Hope professorship, Sir Edward Poulton, had made Oxford the centre for the study of the Darwin-Wallace theory of natural selection, as applied to the coloration and evolution of insects. This could only be explained on that theory. Sometimes it pays an insect to change its appearance according to whether it appears in a dry or a wet season. Poulton pointed out that a dry season is one of scarcity of food, and certain butterflies then remain inconspicuous, and of skulking habits, whereas in a wet season they are quite conspicuously coloured, and they can afford to allow some of the species to be eaten by reason of their numbers. Prof. Hale Carpenter referred to a species (*Charaxes zoolina*) from Africa which is conspicuous in the wet season, but in the dry season assumes a dead-leaf brown, and deliberately hides itself amongst clusters of dead leaves. Such cases afford support to Darwin's theory. It was customary for early entomologists to assume that coloration of the kind was due to the foresight of a beneficent Creator, and many statements were quoted from their writings to show this point of view, although Erasmus Darwin had some very pertinent remarks suggesting that variations in colours had some greater meaning than had then been discovered.

The clarification of the whole subject came when Darwin formulated his theory of natural selection and the preservation of favoured races in the struggle for life. This added zest to the study of entomology and revolutionized the older views. In spite of the rejection of the theory by some biologists nowadays, Prof. Hale Carpenter remarked, "No explanation has yet been put forward which covers the facts of the coloration of insects so well as does the theory of natural selection". Bates first gave a rational explanation of what he called mimetic analogy, now usually termed mimicry. Certain insects will mimic the outward form of others that are distasteful, and the enemy will avoid them, although not really distasteful. At the root of the matter lies the question of memory, and the assumption is that some of their enemies have recollections of distastefulness. "A variation which assumed a mimetic form has a better chance of surviving to reproduce its like by the laws of heredity, and an initial slight resemblance may be perfected into astonishingly detailed mimicry".

In his address to the Botanical Section, Mr. A. J. Wilmott spoke on the "Endemic Flora of Britain". He controverted the generally-accepted theory that the flora of Britain was exterminated in the Ice Age some ten thousand years ago. He held that at its height there were probably many nunataks where plants took refuge, apart from those parts of southern England which were never in their entirety and at one and the same time covered by ice. In addition, there were four interglacial periods during which there was amelioration of climate, when plants could obtain any foothold that they had lost during the severe periods of glaciation. Considerable migration from place to place was evident, during which there was possibly an "orgy of variation". It was mentioned that ten years' work on the compilation of a new flora of Sussex, commenced at the Hastings Congress in 1927, had now brought publication within view, and subscribers and contributions towards publication were needed.

In the Zoological Section, Lord Mansfield gave an address on "Bird-Ringing and Bird Migration". He said that a very small proportion of rings is ever returned, and an endeavour is to be made to reach the peasantry of various lands who never read pamphlets or newspapers, and thus know nothing of the value of the rings that they collect. Experiments he had made have shown that it is not only the desire to avoid cold climates that gives the impetus to migration. A canary and other birds when supplied with food have been seen feeding in the snow in Canada. Birds kept in an aviary have been found to wake up at night, whenever an electric light was turned on, and feed eagerly, birds' digestions being of a rapid nature. Food is what migrants have in view rather than the avoidance of cold. Reference was made to the endeavour now being carried out to induce the breeding of storks in England, and a report promised for next year's Congress. Mr. E. M. Nicholson spoke on the progress of the British Trust for Ornithology.

Of considerable interest and value is the report of the Insect Immigration Committee, conducted under the energetic guidance of Capt. T. Dannreuther. Observers all around the coast have been enlisted in this work, including by permission of Trinity House the occupants of lighthouses and lightships. The greater number of observations of the presence of certain butterflies and moths on land do not demonstrate migratory movements, and thus those made at sea or by the shore have the greater value. Actual movements in definite directions are greatly needed, and thus continuous watch by observers is asked for. In May 1933, undoubted immigrations were noted of *Vanessa atalanta*, which were seen arriving from over the sea on the south coast. These established themselves as far north as Thurso. After September they decreased rapidly in the north, but became more common in the south than at the height of summer. In 1935 the decline in the north was more gradual. *Cardui* (painted ladies) were scarce in 1933 in the Highlands, though common in southern Scotland, and it was noticeable that when they had disappeared, *V. atalanta* still remained common. Much work remains still to be done, and additional observers are needed in this fascinating work.

In the Geological Section, Dr. Dighton Thomas read a paper on "Geology and the Community", and showed how the science touches the common interests of all classes. Much money has been wasted in the past in the search for water, coal and oil, where a little geological knowledge would have avoided the waste. Municipalities are not even now alive to the necessity of taking expert advice about such matters.

Many excursions were made to places of scientific interest. Archæologists visited the Cotswold churches of Fairford, Bibury, Burford and Faringdon. Botanists and zoologists went to the Ruskin Reserve at Cothill, where marsh, fen and aquatic plants were found. Three rounds of visits were made to Oxford colleges, the Bodleian, the Sheldonian, and the Museum of the History of Science, where Dr. R. T. Gunther explained the treasures of the Old Ashmolean.

It was announced that the Congress in 1937 would be held at Hastings under the presidency of Prof. F. E. Weiss, formerly George Harrison professor of botany in the University of Manchester.

Educational Topics and Events

BIRMINGHAM.—At the annual degree congregation, honorary degrees were conferred on Mr. W. B. Grove, a well-known mycologist, and Mr. A. E. Hills, a Birmingham manufacturer to whose generosity the University owes the new chemistry building now being erected.

CAMBRIDGE.—T. R. B. Sanders, of Corpus Christi College, has been appointed University lecturer in engineering.

W. W. Brigden, of King's College, has been elected to the Marmaduke Sheild Scholarship in anatomy. Frank Smart Prizes have been awarded to G. Metcalfe, of Clare College (Botany), and E. T. Burtt, of King's College (zoology).

At Magdalene College, Dr. D. W. Babbage, research fellow of the College and University lecturer in mathematics, has been elected into an official fellowship.

EDINBURGH.—At a graduation ceremonial on July 3 the honorary degree of Doctor of Laws was conferred on the following, among others: Sir Thomas Hudson Beare, professor of engineering and dean of the Faculty of Science in the University; Sir William W. M'Kechnie, lately secretary to the Scottish Educational Department; Prof. Edward L. Thorndike, professor of education, Teachers' College, Columbia University, New York.

OXFORD.—Dr. J. H. C. Thompson, research fellow of Merton College, and formerly of New College, has been elected fellow of Wadham College and lecturer in mathematics—a new appointment.

ST. ANDREWS.—Mr. John N. Wright has been appointed to the chair of logic and metaphysics, vacated by Prof. G. F. Stout. Mr. Wright was appointed assistant to Prof. Stout in the United College in 1920, and in 1924 became lecturer in philosophy in University College, Dundee.

Mr. T. Malcolm Knox, fellow and tutor of Jesus College, Oxford, has been appointed to the chair of moral philosophy vacant by the death of Prof. David Morrison. From 1924 until 1931 he was secretary to Lord Leverhulme, but was appointed in 1931 to a lectureship in philosophy at Jesus College, Oxford. He was junior dean and librarian of his College, a member of the Sub-Faculty of Philosophy, and a member of the Oxford University Appointments Committee.

Science News a Century Ago

John Ericsson's Screw Propeller

ON July 13, 1836, six weeks after F. P. Smith patented his screw propeller, John Ericsson, the famous Swedish engineer, also secured a British patent for a screw propeller, but of a very different design. Ericsson's propeller consisted of two drums each carrying on its exterior helical blades; the blades of each drum being inclined in opposite directions, so that one screw was 'left-handed' and the other 'right-handed'. The drums were fitted tandem-fashion behind the rudder and the invention included an arrangement by which the drums were revolved in opposite directions. The object of the duplex arrangement was to avoid loss due to the rotary motion imparted to the water by a single screw.

Ericsson fitted his propeller to the *Francis B. Ogden* in 1837 and the *Robert F. Stockton* in 1838. In 1837 the *Francis B. Ogden* towed the Admiralty barge from Somerset House to Blackwall and back. Ericsson, however, received no encouragement and afterwards learnt that Sir William Symonds, Surveyor of the Navy, had remarked that "even if the propeller had the power of propelling a vessel it would be found altogether useless in practice, because the power being applied at the stern, it would be absolutely impossible to make the vessel steer."

Biot at the Collège de France

IN its column of "Miscellanea", the *Athenæum* of July 16, 1836, said: "The learned and scientific M. Biot has been delivering some very remarkable lectures at the Collège de France. He has proved, that, by means of polarized rays, it is possible to ascertain the chemical action which takes place between bodies held in solution in various liquids; an action which has not yet been discovered by less delicate means. This is a new branch of science, created as it were by this great natural philosopher, from which the most important and curious results may be expected."

Sir John Herschel and Mr. Somerville

WRITING to Mr. Somerville from "Feldhausen near Wynberg, C.G.H." on July 17, 1836, Sir John Herschel, referring to the honour which had been paid Mrs. Somerville, said, ". . . Though what she has performed may seem so natural and easy to herself, that she may blush to find it fame; all the rest of the world will agree with me that merit of that kind is felt and recognised at length in the high places of the earth. . . ."

"We are all," he continued, "going on very comfortably, and continue to like the Cape as a place of (temporary) residence as much or more than at first. The climate is so very delicious. . . The stars are most propitious, and astronomically speaking, I can now declare the climate to be most excellent. Night after night, for weeks and months, with hardly an interruption, of *perfect* astronomical weather, discs of stars reduced almost to points, and tranquilly gliding across the field of your telescope. It is really a treat, such as occurs once or perhaps twice a year in England—hardly more. I had almost forgotten that by a recent vote of the Astronomical Society I can now claim Mrs. Somerville as a *colleague*. Pray make my compliments to her in that capacity, and tell her that I hope to meet her there at some future session. . ."

Societies and Academies

Paris

Academy of Sciences, June 2 (*C.R.*, 202, 1826–1880).

L. E. DICKSON: Solution of Waring's problem.

JEAN CABANNES and AUGUSTE ROUSSET: Measurement of the factor of depolarization of the Raman lines in gases: nitrogen, oxygen, carbon dioxide.

GEZA KUNETZ: Some properties of characteristic functions.

ALFRED ROSENBLATT: The conformal representation of restricted domains limited by general curves.

A. TOUSSAINT and S. PIVKO: Free plane stream. The influence of the supporting wings on the aerodynamical characteristics.

GEORGES SABATHE: The origin and suppression of the discontinuity in the hydrodynamic resistance of the floats of flying boats.

VICTOR MAITRE: The colour of stars of the spectral types $A0$, $A2$. The hypotheses of a distance effect and an effect of absolute magnitude have been examined separately. From a study of 335 stars of types $A0$ and $A2$, the results can be better interpreted as due to an effect of absolute magnitude than as a distance effect. An examination of the B type stars will follow.

W. ARKADIEW: The magneto-dynamic relation between the viscous losses and the permeability in very weak fields.

THÉODORE V. IONESCU: Luminous discharges observed in the magnetic field at pressures below 10^{-4} mm. of mercury. Detailed description of the light effects observed under varying conditions of voltage and magnetic field. The theory of the phenomena is not discussed.

LÉON CAPDECOMME: The role of the parasite flux in measurements of reflective powers carried out with the aid of the microscope.

ANDRÉ MORETTE: The melting point of vanadium oxychloride and vanadium tetrachloride. The thermal analysis of the system chlorine – vanadium tetrachloride. The melting point of the tetrachloride is $-77^\circ \pm 2^\circ$ C. and of the oxychloride, $-28^\circ \pm 2^\circ$ C. The results of the thermal study of the system chlorine, vanadium tetrachloride are given graphically; they show no indication of the existence of a vanadium pentachloride.

RENÉ WURMSER and MME. SABINE FILITTI-WURMSER. The equilibrium between isopropyl alcohol and acetone in the presence of alcohol-dehydrase.

MME. MARIE FREYMANN and RENÉ FREYMANN: The infra-red absorption and Raman spectra of amides and anilides and the structure of these compounds. The conclusions lead to structures differing from the classical formulæ, and favour the hypothesis of chelation already suggested by several authors.

RAYMOND AMIOT: The adsorption of binary mixtures of acetic acid and of some alcohols in aqueous solution.

MAURICE ENGELDINGER: The study of a colloidal solution prepared starting with resorcinol – formol resins.

MME. LÉONE WALTER-LÉVY: Contribution to the study of the basic magnesium sulphates.

CHARLES DUFRAISSE and MARCEL GÉRARD: Dissociable organic oxides and anthracene structure. The properties of photo-oxyanthracene. From its chemical reactions, photo-oxyanthracene resembles anthrahydroquinone and oxanthrone, with which it is isomeric, but differs in its oxidizing power due to the peroxide function.

Georges Dupont and Raymond Dulou: The pyronenes.

A. P. Rollet: The polymorphism of potassium pentaborate, $K_2O.5B_2O_3$.

Philibert Russo: The Lias at the northern extremity of the Middle Atlas.

Josué-Heilmann Hoffet: The discovery of the Cretaceous in Indo-China.

Aimé Rudel: The flora, fauna and origin of the peperites of the Puy-de-Mur (Limagne d'Auvergne).

Marcel Gautier: The palæogeography of the Nemours (Algeria) region.

H. Grisollet: Study of the light diffused by particles in suspension in the air.

Ong Sian Gwan: The presence of sensitizing antispermatozoids in the blood of man and of woman.

Melbourne

Royal Society of Victoria, May 14.

Ann Nicholls: The mineralogy of the sand fractions of some Victorian soils. A microscopical study of the fine sand fractions of some Victorian soils has indicated that soils on the Jurassic rocks contain abundant orthoclase and plagioclase, suggesting that they are immature. Basaltic soils show quartz, zircon, tourmaline and sponge spicules, which must be due to the addition of foreign material by the wind. The amount of basaltic material present depends on the state of maturity of the soil, as determined by the age of the basalt flow and the slope on which the soil is developed.

R. T. Patton: A fossil *Casuarina* from near Bacchus Marsh, Victoria. Small teeth-like leaves, grooves on the branchlets and fruits are excellently preserved in beds which may be Miocene, as they overlie Oligocene lignites.

A. B. Edwards: Occurrence of almandine garnets in some Devonian igneous rocks of Victoria. Almandine is a characteristic mineral in those Upper Devonian rhyo-dacites of Victoria the magmas of which, at the time of their extrusion, had reached a state of 'silica saturation' in excess of the requirements of their ferromagnesian minerals and felspars. With further crystallization of the magma, the garnet became unstable owing to a dwindling ferromagnesian concentration, and broke down into more stable minerals, such as cordierite and biotite. Because of this, garnets are rare in granitic rocks, except in association with basic xenoliths. This process is not substantially affected by assimilation, so that the garnets appear to be pyrogenetic minerals of a 'discontinuous reaction' type.

Washington, D.C.

National Academy of Sciences, *Proc.*, 22, 249–326, May 15.

Edison Pettit: A second law of the motions of eruptive prominences. These prominences rise from the chromosphere and disappear at great heights during intervals of a few minutes or hours. They rise with uniform motion, modified at intervals by sudden increases as though receiving occasional impulses. From the records of thirty-eight such prominences, it is deduced that, when this sudden increase of velocity occurs, the new velocity is always a small multiple of that immediately preceding it.

C. D. La Rue: The effect of auxin on the abscission of petioles. When the leaf-blades of *Coleus* and *Ricinus* are removed, the petioles develop an absciss layer within a few days, and fall off. Several substances known to contain the growth hormone, applied in agar-agar or lanolin, delay formation of the abscission layer; the most effective is synthetic hetero-auxin in lanoline. Their effect is greater if the plant is kept in the dark.

Chester Stock: Perissodactyla of the Sespe Eocene, California.

F. Zwicky: Extra-terrestrial effects of cosmic rays. Such effects have not hitherto been investigated. It is estimated that the total intensity due to light, atomic and cosmic rays in space is greater than 10^{-3} ergs/cm.^{2} sec. Discussing in particular the long-period variable stars, which have comparatively low surface temperatures, it is suggested that the emission by these stars of the Balmer lines with high intensity may be due to the absorption of such interstellar energy. It is also possible that the mechanical behaviour of extended gas and dust clouds in interstellar space (sharp outlines observed) may be due to corpuscular rays.

C. M. Pomerat and M. X. Zarrow: The effect of temperature on the respiration of the earthworm. Respiratory measurements over the range 9°–27° C. on normal worms, and also on worms from which the supra- or subœsophageal ganglion had been removed, show that there is an increase in rate of gas exchange with rise of temperature, as in other animals the body temperature of which is variable.

H. G. du Buy: The change in the response of oat coleoptiles to growth regulators produced by aging. Response decreases with age at all concentrations of auxin, and the threshold concentration for curvature increases with age. The plants are sensitive to auxin only at a certain stage of development, the duration of which can be varied.

Robert M. Yerkes and James H. Elder: The sexual and reproductive cycles of chimpanzee. Data are given from daily observations of animals at the Yale Laboratories of Primate Biology, and include records of behaviour and reproductive outcome of more than five hundred controlled matings. The sexual cycle is approximately five weeks and the period of gestation eight months.

B. D. Burks: The nearctic Dirhinini and Epitranini (Hymenoptera, Chalcididæ). These parasitic flies exhibit great variations of structure. They are accordingly divided into five tribes, two of which are discussed and keys given.

G. A. Miller: Groups in which the squares of the operators generate a cyclic group.

Edward V. Huntington: Mathematical postulates for the logical operations of assertion, conjunction, negation and equality.

Sumner Byron Myers: Isometries of 2-dimensional Riemannian manifolds into themselves.

J. W. Alexander: On the connectivity ring of a bicompact space.

Edward Kasner and George Comenetz: Conformal geometry of horn angles.

T. Y. Thomas: On normal co-ordinates.

Marston Morse: Functional topology and abstract variational theory.

W. V. Quine: A theory of classes presupposing no canons of type.

Forthcoming Events

FIFTH CONGRESS OF UNIVERSITIES OF THE BRITISH EMPIRE, July 13–17.—To be held at Cambridge. The Right Hon. Stanley Baldwin: President.

July 15, at 10 a.m.—G. H. A. Wilson: "Some Problems which confront Universities".

July 15, at 11.—(1) Discussion on "Provisions in Great Britain for Postgraduate Studies for British and Overseas Students", to be opened by the Right Hon. Lord Macmillan. (2) Discussion on "Functions of Universities in the Training of Teachers", to be opened by Sir Percy Nunn.

July 16, at 10 a.m.—The Hon. H. J. Cody: "The Relation of Canadian Universities to National Life".

July 16, at 11.—(1) Discussion on "Careers for University Students", to be opened by O. V. Guy. (2) Discussion on "General as an Alternative to Specialised Honours Courses", to be opened by Sir Charles Grant Robertson.

July 17, at 10 a.m.—The Right Hon Oliver Stanley: "The Relation of Secondary Education to the Universities".

July 17, at 11.—(1) Discussion on "University Examination Methods", to be opened by Dr. A. W. Pickard-Cambridge. (2) Discussion on "Physical Education in the Universities", to be opened by Dr. Carleton Stanley.

WOMEN'S ENGINEERING SOCIETY, July 17–20.—Fourteenth Annual Conference to be held in the University of Leeds.

July 17, at 7.—Mrs. J. A. Mollison: Presidential Address.

BRITISH MEDICAL ASSOCIATION, July 17–25.—Annual Meeting to be held in Oxford.

Sir E. Farquhar Buzzard: President.

Science in the Public Press

THE desirability of promoting a more intelligent and more intelligible consideration of scientific work and thought in the public Press has often been urged in these columns; and there are signs of increased attention to this need both from newspaper editors and from scientific workers. This is due to several causes. The public expenditure upon scientific research is now large. Government departments which spend money on research, and scientific workers who are supported by public money, feel that the public should understand the value of the work it is supporting. This motive of social self-justification penetrates far more extensively than is generally realized. The Department of Scientific and Industrial Research and the University Grants Committee provide funds which assist a large fraction of all the scientific research at present done in Great Britain.

The circumstances of scientific research in this country have undergone a profound change during the last fifty years. In the nineteenth century, the leaders of research did not consider that social justification of their work was necessary. Providence had placed them in fortunate situations where they were able to indulge their personal intellectual tastes, and though their labours might be of practical value to humanity, or profitable to themselves, this was regarded as a happy accident. They considered that the receipt of a comfortable academic salary or private income did not lay any very pressing obligation on them to use their talents for the extension of scientific knowledge to the community. This attitude was derived from an earlier stage of civilization, when humanity was forced to admire those who could exact support without rendering any corresponding service.

The Greeks despised Archimedes' contributions to mechanics because manual skill in a slave State was disreputable. Until recently a large part of scientific research was done by persons enjoying academic endowments or private fortunes. As they were not directly dependent on the public, they did not see why they should explain what they were doing. In extreme cases, such as that of Henry Cavendish, they did not explain what they were doing even to their friends. A scientific worker in direct receipt of a subsidy cannot reasonably adopt this attitude.

The policy adopted by large industrial corporations of supporting research in order to invent valuable new processes has provided another motive for the extension of public interest in science. Many corporations systematically publish accounts of their researches, partly as a form of advertisement to show their progressive character. They are interested in securing as much public discussion as possible of the scientific principles connected with the goods they wish to sell. In the United States especially, a large amount of advertisement is designed to appeal to the scientific interests of consumers.

The rapid increase in the number of scientific inventions, such as radio, aeroplanes, synthetic plastics, and thousands of other modern objects, attracts the scientific curiosity of the public. In addition, there are the results of decades of the teaching of science in schools, and the spread of the conviction that science is the chief characteristic of the present age. It can scarcely be admitted, however, that the present age is scientific, though science may be prominent in it. Indeed, the development of science throws into greater contrast the unscientific nature of the greater part of modern life. Nothing could be more unscientific than the contemporary armaments race, and the existence of widespread poverty and malnutrition in a period of unparalleled development of the technique of production, and the study of the science of nutrition. An increasing number of citizens are looking to the public Press for explanations of these paradoxes.

It is not necessary to enumerate more reasons why the demand for news and information of science in the Press is increasing. The fact is known to every newspaper editor. Some are puzzled by it, and accept it merely on business grounds. Recent questionnaires on the popularity of different types of articles have shown that scientific articles are more popular than many editors with a literary training had believed.

While nearly everyone admits the increasing demand for news of science, there is general agreement that the demand is not being met satisfactorily. Scientific workers are irritated by inaccurate Press accounts of their activities, and the public is unable to hear of many matters it would like to know. Better methods of handling science in the Press are required. For various reasons the problem is difficult. The mere technical difficulty of explaining science in a style suitable for a newspaper, and yet not obnoxious to men of science, is considerable. The difficulty of popularization is generally underrated. Good popularization requires a breadth of culture in the writer which is not very common among scientific workers, or any section of the population. Few men of science are immediately capable of writing for the Press. In fact, it may be confidently asserted that it is more difficult to earn £300 per annum in writing satisfactory scientific articles for the Press than to earn an equal sum as a research worker. This is one of the explanations why so much newspaper matter relating to science is so bad.

The poor financial rewards of scientific journalism have repelled most able men from the work. The field has been left to a small group which contains an exceptionally large percentage of writers who, for one reason or another, do not fit in very well with the usual professions, where equivalent qualifications can usually command an income of £750 a year in an academic or industrial post. Until newspapers are prepared to pay such a salary for a full-time science editor, they will remain without a representative of science with standing equal to that of a literary editor. The problem is thus, to a large extent, economic.

The creation of a science news agency, like Science Service in the United States, seems to be a more immediately practicable, though less ideal, solution. But there are serious difficulties in creating such a service. The Press includes journals conducted on very different principles, and with very different points of view. The technique of writing for different types of journal varies greatly. Some writers are brilliantly successful with one type of journal, and are complete failures with others. Newspapers are very competitive. Editors in Great Britain always like to have some individuality or exclusiveness in their copy: they use matter from the Press agencies only when they are unable to get special material of their own. Thus a news service tends to start with the neutral characteristics of a stop-gap organization. But though there are difficulties confronting the establishment of a science news service, such a service is particularly necessary in the absence of adequate science reports in the Press, and will always have a useful function, for the same reasons which keep the various general Press agencies in vigorous existence.

Assuming that a science news service is desirable, the next point to decide is how it may best be organized. It would be wise to be clear from the beginning who should control the service. Should the predominance of the control be with science, or with the Press? Different answers might be given to this question in different countries and circumstances. There is little doubt that in Great Britain final control should at the beginning rest with representatives of science. The organizers of such a service should seek endowments from societies and individuals, and the control should be through a committee of eminent men of science. A staff of two or three scientific journalists, whose various styles will roughly suit the various types of journal, should be appointed. A sum of £25,000, or an endowment of £3,000 a year for ten years, might be sufficient for starting the organization under conditions that might lead to great and valuable success. The payment of fairly secure and satisfactory salaries would do much to attract able men to the staff of the service. Until this is done, the presentation of science in the public Press will not be improved, because the sort of ability necessary to solve the problems of the collection and presentation of science news will be much better paid in other fields of work.

Man and Forest in Prehistoric Europe

The Mesolithic Settlement of Northern Europe: a Study of the Food-Gathering Peoples of Northern Europe during the Early Post-Glacial Period. By Dr. J. G. D. Clark. Pp. xvi +284 +8 plates. (Cambridge: At the University Press, 1936.) 25*s.* net.

THE passing of the last Ice Age left northern Europe open to human settlement; but the environment which the settlers encountered was still slowly changing. They had to adjust their equipment to land movements (including the opening of the Channel and the submergence of the Dogger Bank), to the change from a cold 'Pre-Boreal' to a warm continental 'Boreal' climate and then to a moister 'Atlantic' phase, to spread of forests, first of birch and willow, then of pine, then of mixed oak woods, and to consequent alterations in the country's fauna. Of these changes and of the geological, botanical and zoological evidence from which they are reconstructed, Dr. Clark gives a clear account, illustrated with maps and documented with copious references. The successive phases provide not only the background as adjustments to which human cultures must be interpreted, but also the chronological framework in which they must be arranged. Indeed, accepting at least the method of de Geer's geochronology, Clark provisionally offers absolute dates for the climatic phases: 6800–5000 B.C. for the Boreal, 5000–2500 for the Atlantic.

The first colonists are known almost exclusively from their flint artefacts, among which tanged points are the most conspicuous, but Rust and Schwantes found also their 'harpoons' and other tools of reindeers' antler near Hamburg just in time for inclusion in this book. A little later, axe-like and adze-like tools of reindeer antler illustrate men's first efforts at coping with the Boreal forests that were invading the tundras and steppes. Clark accepts Schwantes' thesis that these so-called Lyngby axes of antler are the prototypes of the later north European flint axes, but admits the possibility of their derivation from some still unknown culture to the south-east—a possibility that cannot be excluded while Russia remains almost unexplored. The familiar Maglemose culture (this name, signifying Great Moss, is retained for the whole complex, Mullerup being used for the facies peculiar to Zealand) can then be treated as a further adjustment to the forest environment, though the author insists that its microliths are derived from the Tardenoisian, the spread of which round the fringe of the wooded plains is discussed in a special chapter.

Otherwise the principal novelties in the treatment of the well-known complex are the illustrations of the gravers, included among the relics from the type sites but ignored until Westerby noted them in 1927, and an accurate classification of the various bone points that constitute the best-known type-fossils of the complex. Independently of Bøe (whose work presumably appeared too late for mention), Clark exposes the inaccuracy of the conventional explanation of these as harpoons. He gives a very instructive map of the distribution of selected types from England to the Baltic States (but omitting the new Norwegian finds).

Clark's treatment convincingly establishes the underlying uniformity of culture prevailing throughout the region surveyed—a uniformity that really extends beyond it at least to the Urals. But the differentiation of local groups within this unity is no less interesting sociologically; for it must reflect the crystallization of distinct social units out of an ethnic continuum in Boreal times. It is graphically illustrated by the distribution of types 7 and 14 on Clark's map, and of the Vögtland club-heads and other types recently mapped by Germans. But still more striking is the rarity of axe-like tools in the forested plains east of the Baltic, suggested to the reviewer by a recent examination of Russian collections.

Regional differentiation is more emphasized in Atlantic times. Clark establishes very convincingly the continuity between the Maglemose and Ertebølle cultures in Denmark, and the contrast between the latter and its English and Scandinavian contemporaries. The differences between Maglemose and Ertebølle are due mainly to changed environment, between Ertebølle and say Lower Halstow to the isolation consequent upon land-sinking.

Its comprehensive bibliography, its tables of sites, of fauna and of flora, and its copious and beautifully executed figures and maps, make this book a standard work on the northern mesolithic. Its author's mastery of British as well as Baltic archæology should commend it even to the most insular local antiquary. As an objective record of human adaptation to changing environments and of the divergence of industrial traditions, it possesses a wider historical interest.

V. G. CHILDE.

Invisible Radiations of Organisms

Invisible Radiations of Organisms
By Prof. Otto Rahn. With an Introduction to the Physics of Radiation, by Sidney W. Barnes. (Protoplasma-Monographien, Vol. 9.) Pp. x+215. (Berlin: Gebrüder Borntraeger, 1936.) 13.20 gold marks.

HERE we behold mitogenetic radiation masquerading as the legitimate offspring of biochemistry and the quantum theory, and the unwary reader, finding 'muscle radiation' casually mentioned in a purely physical account of the photo-electric effect, may well suppose the scientific status of the two phenomena to be identical. On reaching p. 55 he may begin to suspect that in reality mitogenetic radiation was quite differently conceived; but up to this point the emission of such radiation by living cells, and even by simple systems undergoing chemical reaction, is treated as a predictable phenomenon related to chemiluminescence, and is described with the same confidence as the dispersion of light by a prism. Even the too remarkable phenomena of 'secondary radiation', involving emission of fluorescent radiation of shorter wave-length and higher intensity than the incident radiation, and its propagation, by successive phases of absorption and re-emission, through an absorbing medium, are made to appear almost as inevitable as Newton's laws of motion.

From p. 55 onwards, apart from a fair discussion of the physical detection of mitogenetic radiation, the book is biological, dealing largely with material which has already been adequately presented by Gurwitsch in his two monographs: the biological detection, phenomenology and significance of mitogenetic radiation. In addition to this, there are a few references to more recent work, accounts of experiments by the author and his collaborators, and some rather uncritical remarks about the alleged lethal effects of menstrual blood on yeast and bacteria.

A brief epilogue is devoted to the question of errors in the detection of mitogenetic radiation and to the attitude of those who remain unconvinced of its existence. Piously hoping for a *rapprochement* between believers and non-believers, Prof. Rahn does not seem to realize that his book is not likely to help in the attainment of that object. The critics ask only that a detailed re-examination of the original mitogenetic effect shall be undertaken by some of those who claim to be able to obtain positive results without difficulty; but Prof. Rahn and his Russian colleagues prefer to write redundant monographs on the ubiquity of mitogenetic radiation, to discuss it in relation to amphibian metamorphosis, parasitism, polyploidy in tomato plants, industrial fatigue, cancer and old age, and to invent queer chain reactions to hide its physico-chemical misbehaviour.

Properties of Iron

The Metal—Iron
By H. E. Cleaves and J. G. Thompson. (Alloys of Iron Research Monograph Series.) (Published for the Engineering Foundation.) Pp. xii+574. (New York and London: McGraw-Hill Book Co., Inc., 1935.) 36*s*. net.

TO the valuable series of monographs on the alloys of iron, issued by the Engineering Foundation, there has now been added a volume dealing with the production and properties of the parent metal in a state approaching purity. Although iron is used in far larger quantities in industry than any other metal, and is not obtainable commercially in such a pure condition as several other metals, such as aluminium and zinc, our knowledge of its exact properties is still very imperfect. There are two main reasons for this fact. With its high melting point and great chemical activity, iron readily absorbs impurities when in the molten state, which are correspondingly difficult to remove, whilst its properties are exceptionally influenced by the presence of even very small quantities of foreign elements. The properties assigned to 'pure' iron in the text-books are mostly derived from commercial materials regarded as approximately pure, or by extrapolation from a series of samples with diminishing amounts of impurity. The results are in either case unsatisfactory.

The present work, by two members of the staff of the U.S. Bureau of Standards, covers the subject very thoroughly, and the volume is indispensable to the scientific metallurgist. The methods used in the laboratory and on the technical scale for the purification of iron are described, and the properties of the purified products reviewed, the treatment being critical throughout, with a useful short survey of the results at the end of each chapter. Electrolysis is commonly resorted to for purification, and this method successfully removes most of the impurities, except nickel and cobalt, but when the deposited metal is brought into a workable form by melting, new opportunities of contamination occur. Published analyses are not a satisfactory guide. As the authors point out, the formidable list of impurities recorded by some workers using refined analytical methods may not indicate that their metal was less pure than other samples, but may be merely evidence of more scrupulous analysis. The work was completed just too soon to include the careful work of Adcock and Bristow, who obtained an exceptionally pure product, using a chemical method followed by repeated fusion in hydrogen and *in vacuo* in vessels of pure alumina.

Much engineering research has been carried out on ingot iron, a low-carbon variety of mild steel which is always segregated, and contains many inclusions. In recent years, carbonyl iron, prepared by decomposing the vapour of iron carbonyl and sintering the product without fusion, has become available, and is the purest form of iron commercially produced at present ; but the cost is relatively high.

The chapters on the physical properties of iron, including the effects of small quantities of each of the impurities usually found in the metal, are most interesting. The allotropic changes occur in even the purest iron, and do not, as was at one time suggested, disappear on the removal of impurities. The magnetic properties are extremely sensitive to minute traces of foreign elements, but in a fashion which does not allow of extrapolation. The difficult subject of corrosion is discussed, the conclusion being drawn that the chemical composition is of less importance than external conditions. It is surprising, in view of the large amount of work included in this review, that the important researches of Bengough and his colleagues are not mentioned, and Bengough's name does not even appear in the excellent bibliography, arranged chronologically, and containing 1,081 references.

Pure iron is a very soft metal, and it is interesting to observe how small is the quantity of an added element which is necessary to give it appreciable hardness. It is this fact which gives to the metallography of iron a special importance, and the system iron–carbon, in particular, has attracted more workers than any other system of metallic alloys. In order to understand the properties of the alloys of iron, it is essential to know those of the pure metal, and the authors have rendered a service in making available a detailed and, on the whole, judicial survey of the whole of this difficult field of study.

C. H. D.

Science and Minerals in the U.S.S.R.

The Scientific Study of Soviet Mineral Resources
By A. E. Fersman. Edited by C. P. Dutt. Pp. 149 +15 plates. (New York : International Publishers, n.d.) n.p.

THE purpose of this book, as stated in the introduction, is to give a brief outline of the achievements of mineralogists and geochemists in Soviet Russia during the last five or six years, in which achievements Fersman himself has played a prominent part.

In its plans for economic development, the Government of the U.S.S.R. early realized the importance of utilizing the mineral resources of the State to the fullest possible extent, and ample provision was made for the investigation and development of these resources. Mineral survey parties, organized on scientific lines, directed their attention to promising areas, and were strengthened as required to carry forward the work of investigation.

One of the most productive of these exploratory parties was the one sent to the Khibin mountain area in the Kola Peninsula, within the Arctic Circle. Here, in an area occupied by nepheline syenites, extensive deposits of apatite were discovered, and as supplies of phosphate were required to meet the needs of Russian agriculture, steps to develop these deposits were taken without much delay in 1929. Within three or four years of the commencement of this undertaking, a carefully planned town had grown up around the apatite mines and quarries. The population of this town at present is about 40,000. The town has a central cinema seating 1,200 people, and has also a fine park.

Rivalling the remarkable mining enterprise at this locality, 2° within the Arctic Circle, is an equally remarkable agricultural enterprise, also organized on scientific lines. Peat bogs have been cultivated, and by using nepheline and apatite powder as a fertilizer, forage grasses are being grown. One farm has a herd of a thousand cows, in addition to vegetable gardens. From the greenhouses of these gardens, the population is supplied with fresh cucumbers and tomatoes. It is hard to believe that life at this locality is free from inconveniences, but these do not enter into Fersman's account. Whatever these may be, the enterprise is indeed a remarkable one. With a present annual output of two million tons of mineral, and a prospective output of seven million tons in 1937, things look promising in this wonderful arctic town.

Among other discoveries and developments mentioned all too briefly in this book are those of the potash deposits of Solikamsk in the Urals, and many other deposits the exploitation of which promises to have important effects not only in the U.S.S.R., but also in the world at large.

The book deserved to be edited, printed and published in better style; but even as it is, and in spite of its somewhat extravagant appreciation of the part played by Russian workers in the development of geochemistry, it will be welcomed as a useful account of tendencies of thought and practice among these U.S.S.R. workers, who are much to be congratulated on the vigorous efforts they are making to establish a stronger scientific foundation than has hitherto existed for the study of minerals and mineral resources.

Memoirs on Systematic Zoology

Temminckia:
a Journal of Systematic Zoology. Edited by Prof. Dr. H. Boschma. Vol. 1. Pp. v + 320 + 9 plates. (Leiden: E. J. Brill, 1936.) 13.50 fl.

THIS new periodical is designed to afford a means of publication for memoirs on systematic zoology. It is named in honour of C. J. Temminck (1778–1858), one of the most distinguished naturalists that Holland has produced and the first director of the great Rijksmuseum van Natuurlijke Historie in Leyden. Its scientific standing is assured by the fact that the editor is the present director of the museum, Dr. H. Boschma, while the name of the publisher, E. J. Brill, is a guarantee of typographical and technical excellence. Unlike most journals of the kind, it will appear only in bound volumes, of which one or two, each of some 320 pages, will appear annually.

The first volume, besides many text-figures, includes nine plates, of which one is in colour. Of the seven memoirs published in it, five are in English and two in German. Four of the authors are Dutch, one German, one Austrian and one American. All the memoirs except one deal mainly with the fauna of the Dutch East Indies.

The first paper, by Dr. G. C. A. Junge, is a faunistic one, dealing with the birds of Simalur and some other islands off the south-west coast of Sumatra. It includes field notes by the collectors on habits and distribution of the species dealt with. C. J. Keijzer writes at length on "Variability in East Indian Foraminifera" and concludes that the supposed trimorphism and polymorphism of certain species have no real existence, but are due to superficial observation of continuous series of variations superimposed on the well-known dimorphism. It is to be gathered from the paper, however, that the life-cycle of the Foraminifera is not so simple or so well-understood as might be supposed from the usual text-book accounts of it.

A revision of the flying lizards of the genus *Draco* by Willi Hennig is based on examination of the material in many museums, gives statistical analyses of measurements, and discusses the geographical relations of the various "Formenkreise".

A paper on the use of the generic names *Tethys* and *Aplysia* among the Mollusca is surely the most fully documented discussion on a point of nomenclature ever published, the list of references at the end extending to more than eighteen pages. The author, Dr. H. Engel, makes out a strong case for submission to the International Commission on Zoological Nomenclature for suspension of the rules in order that the traditional use of these two names may be retained.

Dr. Koumans describes, with statistical data, evidence for an increase in the number of scales during growth in a species of fish. As the number of scales has hitherto been regarded as a constant specific character, this conclusion will have important results for systematists. In the concluding two papers of the volume, F. Spaeth revises the Australasian beetles of the group Cryptonychini, and Austin H. Clark describes the unstalked crinoids of the *Snellius* expedition.

Every systematist knows that it is comparatively easy to find editors willing to accept short papers describing a few new species. Every such addition to the Systema Naturæ, however, demands some modification, although maybe very little, in the diagnoses of previously recognized species, and there comes a time when a revision of a whole group, a genus or a family, must be taken in hand if the system is not to fall into confusion. When an author is courageous enough to attempt such a revision for an extensive group, it is often hard to find a periodical in which it can be published, especially if it is to be adequately illustrated. It has not infrequently happened that such a revision has been laid aside for years after being completed in default of any means of giving it to the world. It is, therefore, a hopeful sign of reviving interest in systematic zoology that a journal should have been established in which important and lengthy memoirs of this kind may find a place.

W. T. CALMAN.

Indeterminism and Psychology

Déterminisme et variabilité dans le comportement des organismes

(Exposés de biométrie et de statistique biologique, 7.) Par Prof. W. J. Crozier. (Actualités scientifiques et industrielles, 261.) Pp. 57. (Paris: Hermann et Cie., 1935.) 15 francs.

THE physicists have gone on strike against determinism and have called on the psychologists to come out in sympathy, but the psychologists can see no logical connexion between the physical problem and the psychological problem. It appears that the physicist can never know the facts about a single electron and can only predict the behaviour of aggregates. An individual animal represents a large aggregate of electrons and other units, and the fact that the behaviour of the individual units cannot be predicted does not necessarily imply that the behaviour of the aggregate is not governed by laws as rigid as those which govern the behaviour of a similar mass of inanimate matter. The difficulties of prediction appear to be due to the complexity of the problem rather than to any fundamental obstacle to observation. The psychologist is presented with a glut of facts about each individual and can see no reason why he should not explain the processes which govern individual behaviour, but such knowledge is likely to play a less important part in the world than a knowledge of the behaviour of aggregates of animals. Prof. Crozier, of Harvard, who has devoted the last ten years to the study of the behaviour of aggregates of rats, has published the summary of his results now under notice.

The evidence may be illustrated by describing a typical experiment. A rat is placed on an inclined plane in the dark, and its movements are recorded by photographing the movements of a patch of luminous paint on the rat's back. The rat knows that a suitable reward awaits it at the top of the inclined plane, and it therefore runs uphill in a series of short straight dashes. The angle between the movements of the rat and a horizontal line in the inclined plane (θ) measures the accuracy of the rat's judgment, which must depend on sensations in the muscles of the rat's legs. When the results obtained from a large number of rats are averaged, their behaviour is found to be governed by laws. For example, the component of gravity in the direction of maximal slope will be proportional to sin α. As the slope increases, the accuracy of the rat's judgment increases in such a way that, like other similar curves depending on sensation, the curve connecting θ and log sin α is shaped like a prolonged *S*, being approximately straight in the middle range.

The curve obtained from a homozygous colony of rats is constant and typical of that colony. If two colonies interbreed, the factors on which the position of the curve depends are inherited according to Mendelian laws. The variability of the animals was estimated by calculating the standard deviation of the observed values of θ. Various conclusions are reached regarding the correlation between variability and slope. Different homozyous colonies of rats showed characteristic different degrees of variability, the inheritance of which has been studied.

Prof. Crozier discusses the philosophical implications of his results, which he considers to be opposed to the opinions of those physicists who would extend the principle of indeterminism to vital phenomena. On the other hand, he does not claim to be able to predict the behaviour of an individual rat any more than the physicist can predict the behaviour of an individual electron. He can, however, predict the behaviour of the average rat just as the physicist can predict the behaviour of the average electron. If methods such as those of Prof. Crozier can be extended to predict the behaviour of the average man, they may play an important part in deciding the destinies of nations.

(1) La radiation cosmique

Par P. M. S. Blackett. 1 : Aperçu général. Pp. 23+4 plates. 10 francs. 2 : La méthode de la chambre de C. T. R. Wilson (commandée par compteurs de Geiger-Müller). Pp. 25+3 plates. 8 francs. 3 : L'action du champ magnétique terrestre. Pp. 20+2 plates. 7 francs. 4 : La perte d'énergie par ionisation. Pp. 21+7 plates. 10 francs. (Actualités scientifiques et industrielles, 230–233.)

(2) Rayons cosmiques

Par B. Rossi. (Exposés de physique atomique expérimentale, 4 : Actualités scientifiques et industrielles, 248.) Pp. 48. 12 francs.

(Paris : Hermann et Cie., 1935.)

(1) THESE small books constitute the only connected account of cosmic rays which is available; and although the lectures on which they were based were delivered two years ago, the account given largely represents existing knowledge, and the problems stated remain mostly unsolved. The first part contains a general and historical account; the second deals with the technique and results of the counter-controlled Wilson chamber introduced by Prof. Blackett. This part contains the account of shower production. The third part is specially valuable. It provides a simplified treatment of the paths of electrified particles in the magnetic field of the earth, and the consequent effect of the field on the distribution of cosmic rays over the earth. The original papers in which this theory was developed by Størmer, Lemaître and Vallarta and others are difficult and in some cases inaccessible. The fourth part deals with the behaviour of very fast particles passing through matter. The details of the processes involved are still uncertain both in experiment and theory. They are at present the subject of intensive investigation, and some progress has been made, particularly in connexion with shower production.

(2) This brochure is more limited in scope than those by Prof. Blackett; it is concerned very largely with Prof. Rossi's own experiments on the cosmic rays, by the coincidence counter method. The experiments include analyses of the rays by absorption and by azimuthal distribution, a study of the effect of the earth's magnetic field, and a study of shower production.

Index Generalis

Année 16, 1936. Annuaire général des Universités et des Grandes Écoles, Académies, Archives, Bibliothèques, Instituts scientifiques, Jardins botaniques et zoologiques, Musées, Observatoires, Sociétés savantes. Publié sous la direction de Dr. R. de Montessus de Ballore. Pp. vii+2482. (Paris : Éditions Spes, 1936.) 225 francs.

THIS most recent edition of an extremely useful source of information concerning the universities, etc., of the world has the same format as its predecessors. All information has been obtained from official sources, thus marking the work as an authentic book of reference.

The first part of the volume gives details concerning the officers, professors and other teaching staff, laboratories and attached institutes of the universities of the world, though, unfortunately, those of the U.S.S.R. are again missing. This is through no fault of the editor of the "Index", who states that he has made repeated efforts to obtain the necessary information. This section occupies 1,213 pages of closely printed type. The next section, occupying 97 pages, supplies information concerning the personnel, publications, instruments, etc., of the astronomical observatories of the world. This is followed by 291 pages concerning libraries and archives. The next 139 pages deal with scientific institutes, such as museums, botanical and zoological gardens, biological laboratories, meteorological and other stations, etc. Societies and academies (with names of members of the more important) occupy the remainder of the text (190 pages). The general name index at the end contains about 95,000 names—a veritable mine for reference purposes; there is also a general geographical index whereby it is easy to trace institutions.

We know of no other single volume publication which brings together in this way so much information regarding the learned world.

The Kātkāris :

a Sociological Study of an Aboriginal Tribe of the Bombay Presidency. By A. N. Weling. Pp. vii+156+15 plates. (Bombay : The Bombay Book Depot, 1934.) n.p.

MR. WELING'S sociological study of the Kātkāris, a criminal tribe of the Bombay Presidency, who survive in considerable numbers in the hilly districts of the Deccan, has appeared at an opportune moment. Not only has there been a tendency to confuse them with the Kunbi, from whom indeed it is not easy to differentiate them, but also, like other aboriginal tribes of India, their institutions are subject to influences which tend progressively in the direction of modification. This process is likely to be intensified rather than arrested among tribes, who still possess something of the hunting culture and of the animistic and magical beliefs, which are of an abiding interest for the anthropologist.

Guide to Philosophy

By C. E. M. Joad. Pp. 592. (London : Victor Gollancz, Ltd., 1936.) 6*s*. net.

THIS is one of the books which will help considerably the case of philosophy as a subject of fundamental interest and importance. It is held in many quarters that without some knowledge of philosophy, the education of a citizen is far from being complete. Those who oppose this view will no longer be able to point to the lack of reliable and interesting books on this subject; for Mr. Joad provides them now with a practical answer in his "Guide to Philosophy". The subjects discussed in this lucid and attractive work are too numerous and too complex for even a brief review. It will suffice to say that the beginner and the specialist alike should derive both profit and enjoyment from its perusal. T. G.

Revision of Ordnance Plans from Air Photographs

By Colonel H. L. Crosthwait, C.I.E.

IN the Interim Report of the Departmental Committee on the Ordnance Survey, discussed in NATURE of May 2, p. 719, reference is made to the employment of air photographs as a means of speeding up the revision of the 25-in. Ordnance plans. It is proposed in this article to indicate in general terms how this can be done.

The area it is proposed to revise is divided up into rectangular blocks of about 10 miles side. The aircraft, carrying a camera* which automatically exposes a roll of photographic film at pre-arranged intervals, is flown to follow a straight course over the ground, and parallel strips are photographed so as to cover the area as shown in the diagrammatic illustration (Fig. 1). For this particular purpose a lens of 20-in. focal length is employed, from a height of about 8,000 feet, giving a scale of approximately 1/5,000. These photographs are afterwards enlarged without rectification to a scale of 25-in. to the mile or 1/2,500. During the flight, the exposure of successive photographs of a strip is so timed that they overlap each other in a forward direction by about 60 per cent, and the strips are arranged to have a lateral overlap of about 25 per cent. If the work is skilfully carried out, the whole area should be covered by strips of photographs without leaving any gaps. The chief object, among others, of giving the photographs an overlap of 60 per cent, is that adjacent photographs of the same strip may be viewed in a stereoscope, which gives an impression of the ground in relief, greatly facilitating the interpretation of objects which might otherwise be doubtful.

It will be noticed that each object is photographed at least twice. Only in the case of level ground where the exposure has been made with the axis of the camera pointing vertically downwards, and where the lens used covers the film without distortion, will the resulting photograph give an accurate map representation of the ground as seen from the air. In practice, the two conditions of a vertical axis and level ground are scarcely ever realised, while lenses are now made practically free from distortion within the limits they are required to cover. It becomes necessary, therefore, to subject the photographs to some form of rectification in order to counteract the effect of camera tilt, which should be kept as small as possible, and the deviation from the level of the ground. This can be done in several ways, but since we are only dealing with the application of air photographs to the revision of the 25-in. plans, we need only mention the method used for this particular purpose. There are few instances where there is not sufficient control on the old plan, in the form of unaltered detail, which can be recognised both on the plan and on the photograph. It is this control which is made use of in the epidiascope. Space will

* The camera used is known as the "Eagle", made by The Williamson Manufacturing Co.

not admit of a full detailed description of the method or instrument, but we can indicate, in general terms, how the revision is carried out with the epidiascope.

The enlargement, derived from the negative taken from the air, which is, as stated, approximately on a scale of 25-in., is carefully examined with the old plan, and new detail is inked up in red. In doing this the draughtsman is aided by the stereoscope, in which has been placed the pair of overlapping photographs relevant to the area under revision. He then selects suitably placed and well-defined points of detail appearing both on the photograph and the old plan, to form triangles covering the area, later to be fitted to the plan in the epidiascope.

The ideal triangle for rectification would be one which embraced an area on a uniform slope proceeding from the base of the triangle. With this object, points selected should be sited, if possible, on high ground and at the bottom of valleys. For this purpose the 6-in. contoured map can be consulted, assisted by the relief view of the area in the stereoscope. The Ordnance Survey employs a modified form of epidiascope* in which the movements have been simplified. It consists of a horizontally placed photo-board over which has been inverted an ordinary camera the back of which forms the plan-board. The photo-board is capable of being tilted about a horizontal and vertical axis. To it the photograph can be secured in any desired position under a sheet of plate-glass on which the two axes are marked. The photograph is set so that the base of the triangle to be revised coincides with the horizontal axis, with its mid-point at the intersection of the two axes. An image of the highly illuminated photograph is formed on the matted surface of a sheet of drawing celluloid, on which has been printed, in grey, an impression of the old plan, placed on the glass camera back or plan-board. The image of the base of the triangle being revised is made to coincide with the corresponding base on the print of the old plan, any small difference of scale being adjusted by a slight movement of the camera lens. The photo-board is then tilted so as to make the triangles fit one to the other. The new detail, which has already been inked up on the photograph, is then drawn in on the celluloid print of the old plan. The same process is repeated, triangle by triangle, until the whole area has been revised. This drawing forms the 'field trace', but

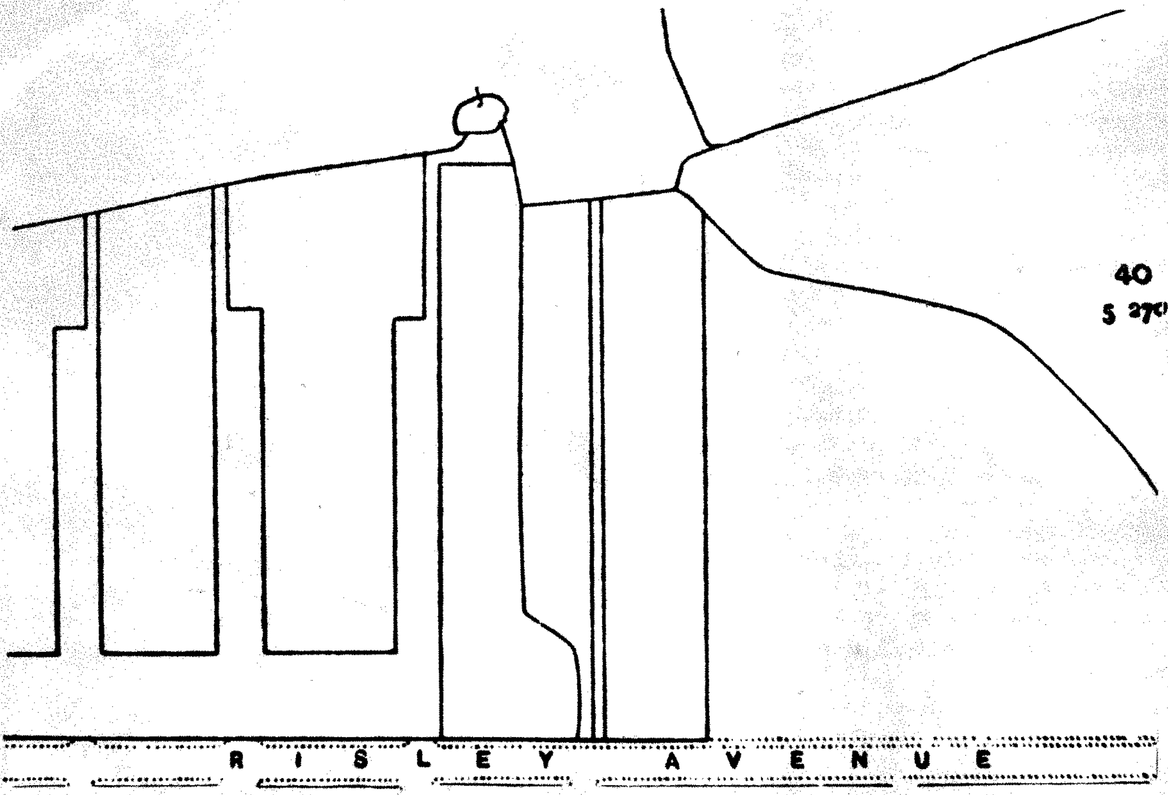

FIG. 2. Air survey of Tottenham. Reproduction of a section of a 25 in. Ordnance plan representing the area covered by the air photograph (Fig. 3). This plan was revised in 1913. Reproduced from the Ordnance Survey Map, with the sanction of the Controller of H.M. Stationery Office.

* For a full description of the epidiascope made by Messrs. Barr and Stroud, see "Surveying from Air Photographs", by Capt. M. Hotine, R.E.

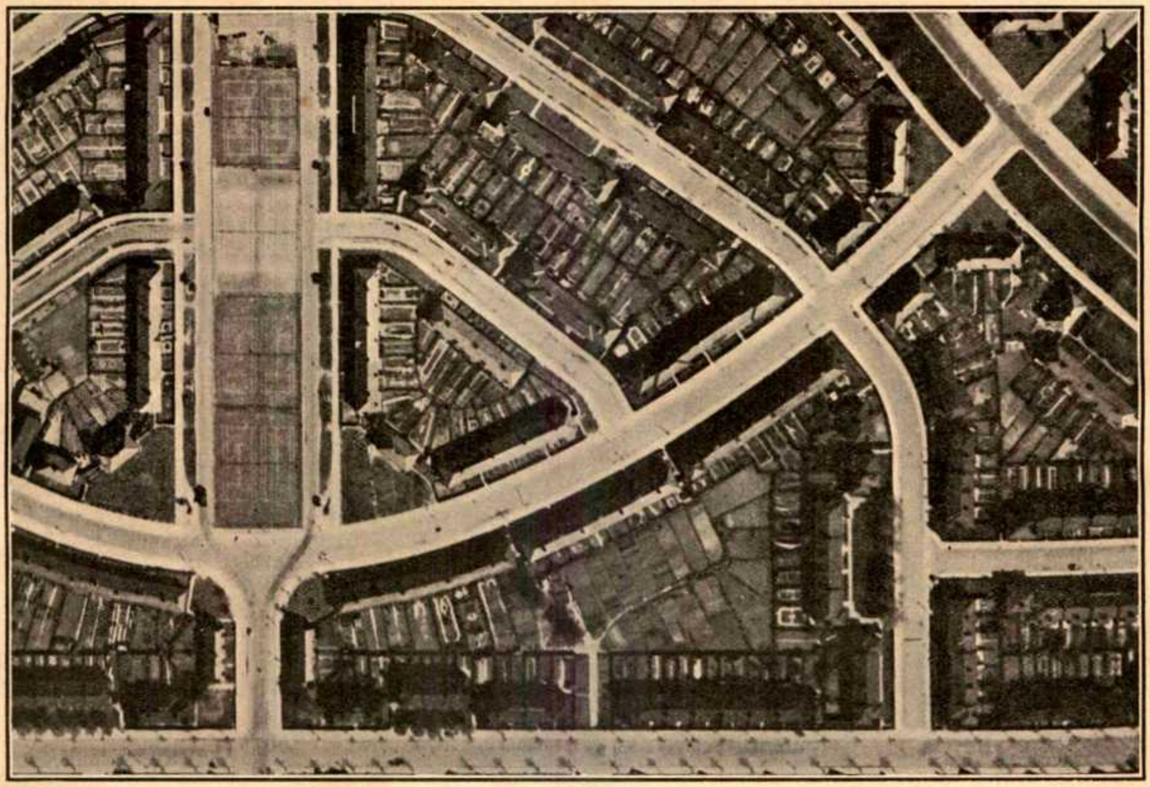

FIG. 3. Air survey of Tottenham. Vertical air photograph taken in June 1935 of same area as Fig. 2, scale 25 in. to a mile. By permission of Aerofilms, Ltd.

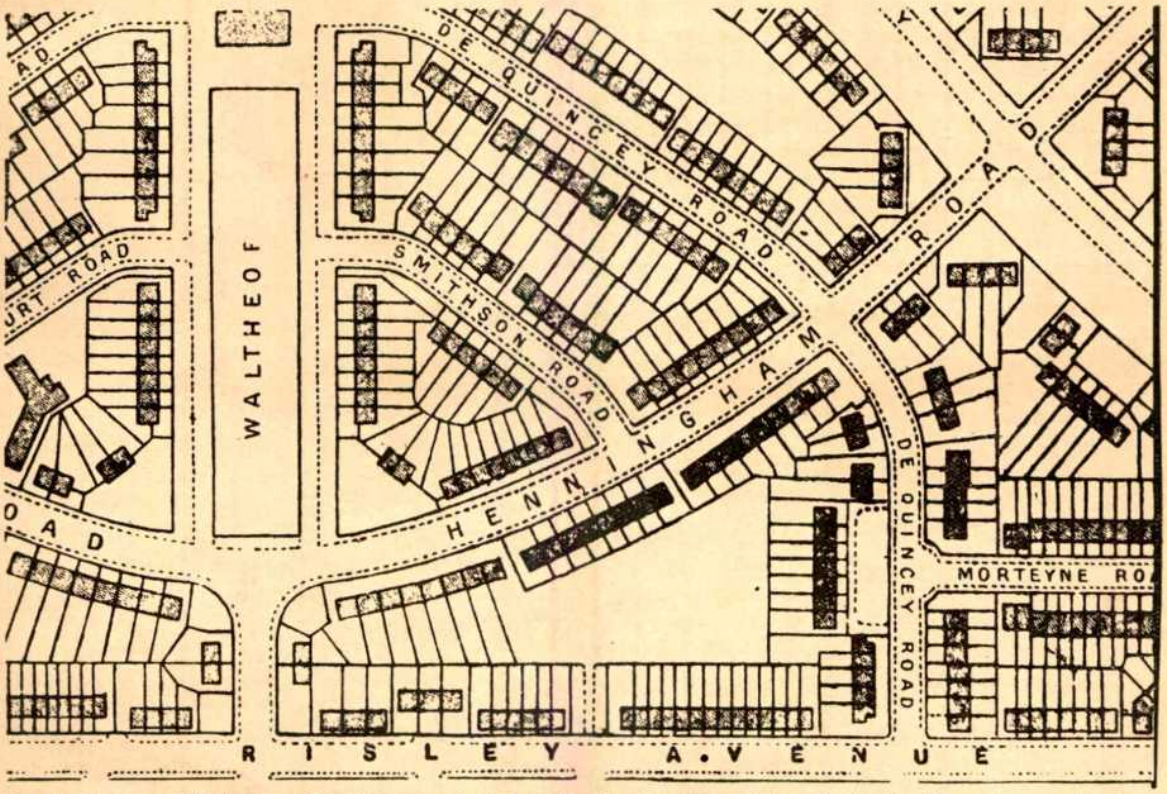

FIG. 4. Air survey of Tottenham. Resulting plan, scale 25 in. to the mile, plotted from photograph (Fig. 3). By permission of Aerofilms, Ltd.

since it is deficient in new names, boundaries and details such as wire fences, which fail to show up on the photograph, or which have been obscured by shadows, it is taken into the field for final revision. From it, when finally revised, the fair plan is drawn in the ordinary way. This, shortly described, without going into detail, is the process employed in revision from air photographs using the simplified epidiascope.

Owing to the small tilt of the photographs, which should not exceed some 2°, and the small area embraced by the triangles, the residual errors due to the theoretical inexactitude of the epidiascope design are so small as to be negligible. The advantage of the modified machine is that it is cheap to construct, a consideration of importance where a good many of them are required to deal expeditiously with a large number of photographs; also it is simple to operate.

Fig. 2 is a reproduction of a portion of an old plan; Fig. 3 a photograph of the same area as it now exists and Fig. 4 the resulting plan plotted from the air photograph.

Archæological Discoveries at Předmost

THE site in Moravia known to archæologists as Předmost actually is, or was, a small hill to the west of the little village of Předmosti, which lies about two kilometres north of Přerov, a junction on the Central European line between Warsaw and Vienna. The hill rose to a height of forty metres above the marshy plain, and was known locally as "Hradisko" (oppidum), evidently having served the inhabitants as a place of refuge in time of war. The substructure of the hill consisted of two limestone rocks joined by a saddle of yellow brick-earth, or loess. The complete quarrying away of one of these rocks many years ago has exposed the face of the loess, and at the base level of the rock in a band of darker deposit have been found relics of prehistoric man in such a quantity and of such a character as to justify the verdict that this is one of the most important palæolithic sites ever discovered.

The former inhabitants had evidently used the rock as an *abri*, or shelter, and had lived by hunting, mainly of the mammoth. Relics of this animal are almost innumerable. A thousand teeth and five milk-teeth have been found, and of the tusks, complete or broken, there are some hundreds. In the first series of explorations of the site, no less than twenty thousand implements of stone, bone and ivory were collected, while the carvings and engravings of ivory and bone are æsthetically and culturally of great interest and importance. The outstanding feature in the discoveries which have been made, however, is an assemblage of the skeletal remains of early man, in which twenty individuals were represented in a single find. The ethnic character of these individuals is no less interesting than the conditions in which they were found.

The first recorded discovery at Předmost was made so long ago as 1571, when "giants' bones" were discovered by John Blahoslav; but it was first recognised as a palæolithic station by Dr. J. Wankel in 1880 and 1881 as the result of an investigation which had begun in 1878. The great explorer of Předmost, however, was K. J. Maska, a schoolmaster, who first turned his attention to the site in 1882, and excavated it systematically and continuously in the ten years 1884–94. It was in this last year that he made his sensational discovery of human remains, when, as already mentioned, skeletons and parts of skeletons representing twenty individuals were found in a small space, an elliptical grave, measuring 4 metres long by 2·5 metres wide by 30 cm. deep. These remains were closely packed, side by side and one upon another, in a crouched position, the heads in most instances towards the north. They lay in the loess above undisturbed quaternary deposits, but separated from them by a calcareous layer 30–50 cm. in thickness. Above the skeletons was the complete skull of an Arctic fox, at the north-west edge was a fragment of the shoulder-blade of a mammoth, which had been graven by a flint tool, and at the south-west lay a complete mammoth shoulder-blade. Two lower jaws of the mammoth, found two metres away, may be related to the burial. Other finds adjacent were fragments of flint and jasper and carbonized bones. Stones to a thickness of 40 cm. had been piled above the interment. Nevertheless, gnawed human bones nearby, and the incomplete condition of some of the remains, suggest that these stones had not availed to keep away beasts of prey.

Unfortunately, no photographic record or drawing was made of the find; and discrepancies in detail have gained currency in accounts of the discovery. The finds associated with the skeletal remains and their position mentioned above are those recorded by Dr. J. Matiegka, to whom Maskra's material was entrusted.

This interment is evidently a communal grave, though whether it was the result of an epidemic or some other simultaneous catastrophe, or represents a succession of burials, thus accounting for the evident disturbance of the remains, there is nothing to show. There are sufficient close resemblances between individuals, some of them inherited, to warrant the conclusion that, if not all of one family as Maska thought, they were at least members of a single familial horde.

Maska's work was followed up by M. Kříž, a lawyer, who carried out excavations in 1894–96. The great collections formed by these two investigators have now been placed, with other valuable archæological and palæontological material brought together from different parts of the country, in the Provincial Museum of Moravia at Brno, where they are in the care of Prof. D. K. Absolon, curator of the Quaternary Collections.

Maska spent the remainder of his life at work on his material from Předmost; but his financial circumstances did not permit him to devote to it the time and attention it demanded. He died while his work was still incomplete in 1916, and Kříž died in the same year.

After the Great War, the interest aroused by the discoveries of early man in Moravia, evidently a 'gate of entry' for early migration into Central Europe, led to more systematic study. Chance favoured the resumption of investigation at Předmost. Further commercial exploitation of the remains of the hill for brick-making purposes opened up the loess deposits by trenches. Important discoveries followed and the Government intervened, taking over the site and entrusting its further investigation to Prof. Absolon, whose discoveries date from 1924.

With the aid of later investigation, it is now possible to obtain a truer perspective of the whole site. The occupation level appears as a darker horizontal band in the yellow clay at a depth of one to four metres and 20–70 cm. in thickness, its extent being estimated at 6,700–10,000 cubic metres. There are three main centres of accumulation, of which one is a domestic hearth with broken bones and implements of stone, the second a hearth of greater extent, which may have served for the preparation of food, with larger bones and finer implements, and a third of indeterminate purpose, consisting of a quantity of varied débris, without order and including bones of every kind, among them whole quarters, such as mammoth's feet, part of the backbone of a horse, etc. Some, however, show signs of arrangement, as for example a pile of thirteen mammoth tusks and four skulls placed side by side.

The vast wealth of objects which now form the collections from Předmost—implements of stone, bone and ivory, carvings and engravings on ivory and bone, personal ornaments of various materials and the like, the human skeletal remains, as well as the remains of the mammoth and other quaternary fauna—reveal the mode of life of the primitive hunter in quaternary Europe in a manner and to an extent which cannot be equalled on any other site, though with it is comparable the site of the horse hunters of Solutré. The development of its art is especially noteworthy. Certain objects, especially a remarkable figure of a mammoth in ivory, are characterized by a naturalism, comparable with the best produced by palæolithic man elsewhere. Here also are the characteristic corpulent figures, woman or divinity. In striking contrast is the work of another 'school', a school with a marked tendency to conventionalize, which culminates in a female figure engraved on a tusk, in lines which are entirely geometrical. It has been suggested that the two schools represent the influence of two distinct races, which met at this point.

The racial characters and affinities of Předmost man have been the subject of considerable discussion; but as such analyses have been based upon photographs and casts, certain features have been stressed unduly, and an authoritative and first-hand account of the remains has long been desired. Whereas many of the authorities concur in showing a tendency to attach too great a significance to the resemblances between Předmost man and Neanderthal man, it stands to the credit of Sir Arthur Keith's acumen and appreciation of the essential quality of the remains, that while recognizing the importance of the great size of the skull and the massive character of the attachments for the muscles, he has been emphatic in claiming an essentially 'modern' character for Předmost man; and further, while pointing out the marked difference between the sexes, he has not been prepared to go so far as those who hold that it is sufficient to justify the allocation of the woman to a different racial category.

The skeletal material available for discussion of the racial character of the people of Předmost, of which the crania, some represented by fragments only, have now been described, and their evidence analyzed, for the first time by Dr. J. Matiegka*, whose paper has only just recently become available, is regarded as representing twenty-six individuals. To this must be added a further discovery by Prof. Absolon in 1929. Of the material found by Maska, fifteen skeletons were fairly complete, while the remaining material was judged to belong to five individuals. Of the fifteen four were, comparatively speaking, well preserved. Eight of the twenty were adult, three being female, two adolescent, one male and one female, seven were children less than ten years of age, and three were infants of under one year.

* Česká Akademie Věd a Umění (Académie Techèque des Sciences et des Arts). Trída 2: Anthropologica. Homo Předmostensis fosilní člověk z Předmostí na Moravě. 1: Lebky. (L'Homme fossile de Předmostí en Moravie. 1: Les crânes.) By Prof. Dr. J. Matiegka. Pp. 145+16 plates. (Praha: Česka Akademie Věd a Umění, 1934.)

Of the adults, the two best preserved were a male and female between the ages of thirty-five and forty years. They are regarded as type specimens of the race. The two well-preserved adolescents approximate closely to them, due allowance being made for the difference in age. The adult male, in particular, shows the close resemblance to Neanderthal man in a number of characters, notably the prominent supraorbital ridge, or torus, the low retreating frontal bone, and so forth. Indeed in its approach to early palæolithic man, this skull, Dr. Matiegka points out, is very near the border-line of the extreme lower range of 'modern' skulls. On the other hand, in certain features, such as for example the possession of a well-marked, if not prominent chin, and the absence of the characteristic prognathism, it is essentially modern.

All the individuals represented at Předmost, with one exception, are sufficiently homogeneous to be regarded as belonging to a single race. Dr. Matiegka stresses in particular their slender character, seen also in the long bones, their light weight, and in the bones of the skull their thinness, features in which they are distinguished from man of the earlier palæolithic period, and to be viewed in relation to size and capacity. In virtue of pronounced Neanderthaloid characters, Předmost man may be regarded as standing morphologically midway between Neanderthal man and modern man, but not in any genetic sense.

In all its dimensions the Předmost skull, both male and female, is within or well above the average of the modern European. The head length ranges from 189 mm. to 201 mm. male, and 185 mm. to 191·5 mm. female; breadth 139 mm. to 145 mm.; height 133–136 mm. In relation to the great size of the skull, the figure for height appears low, but actually it is above the modern average. The cephalic index varies from 70·15 to 77·63, being slightly higher in the women and children than in the men. The contour is ovoid. The cranial capacity is high, 1,578 c.c. male, 1,520 c.c. female, as against 1,475 c.c. male and 1,300 c.c. female in the modern European.

The development of the supraorbital ridge, assuming in certain skulls the character of a torus, appears also in the women and is even perceptible in the children. The sutures are simple; but in all the skulls there are Wormian bones.

The face is high, especially in the upper part, lower in the woman than in the man. The orbits are low, quadrangular and set slightly on the bias in both sexes. The nose is narrow and prominent in the men, broader in the women. The lower jaw is large, corresponding with the size of the skull, but notwithstanding its massive appearance, largely due to the disproportionate strength of the muscular attachments, it is slender in proportion to its size. The chin is slightly receding in relation to the alveolar projection, but there is a well-formed mental tubercle. The form of the jaw is modified by muscular pull. The teeth are well preserved. They are large. There is one apparent case of caries. At least two skulls have lost teeth during lifetime. The teeth are much worn down, the wear already beginning to appear in a boy of ten to twelve years. There is also evidence of a peculiar form of attrition of which the cause is obscure. It is more marked on the right side than on the left, and on that side in the upper jaw more than in the lower. It affects the first molar, the second showing it, if at all, only in a slight degree. It has been suggested that this is due to a custom of carrying a pebble in the mouth continuously, though for what reason is not apparent. In view of the cold climate and its continuous use, it could scarcely be for the purpose of alleviating thirst.

In considering the affinities of the crania of Předmost man with those of other forms of Quaternary man, too much importance must not be attached to the resemblances to Neanderthal man, which have been noted in the first-named. They do not warrant the conclusion at which some anthropologists have arrived that Předmost man represents the stage of transition in a series which extends from Neanderthal to modern man; nor are they the results of a cross between Neanderthal and Aurignacian man. They are due, it must now be held, to simple convergence.

Of the types of 'modern' man of Quaternary age to which the Předmost crania may be related, Grimaldi and Chancelade may be ruled out, notwithstanding affinities to the latter, which have been noted. Předmost stands with Brno I and Brno II, distinct from, but closely related to Oberkassel, with the female Oberkassel as a transitional form. In general terms, it is a simple variant of the Cro Magnon race.

This interpretation of the skeletal evidence is in sufficiently close agreement with the geological and archæological evidence. The fauna of the loess beds points to a rather cold climate of tundra type; while the culture of the settlement, which Maska thought to be Solutrean, is now regarded as developed Aurignacian, the Abbé Breuil would hold with strong Solutrean influence from Hungary, but which Prof. Absolon considers entirely Aurignacian, though of later date than Vistonice, the Moravian station which corresponds to the Upper Aurignacian of France.

News and Views

Native Policy in Africa

A MOTION by Mr. de Rothschild in Committee of the House of Commons on July 9 to reduce the Colonial Office vote initiated a debate on colonial administration with special reference to East Africa, and afforded Mr. Ormsby-Gore as Secretary of State for the Colonies an opportunity of making an important statement in reply, in which he touched upon a number of matters affecting native interests. As an earnest of a promised expansion in education when resources permit, he referred to the provision forthwith of a central institution in Uganda, which would extend facilities for higher education throughout East Africa. He also showed that he is fully aware of the necessity for considering the possibility of regulating the movements of emigrant labourers, to which attention has been directed recently, more especially by conditions in Nyasaland (see NATURE, June 6, p. 921). His most important pronouncement, however, was concerned with the difficult and controversial question of the allocation of land as between native and settler in Kenya. He announced that two orders arising out of the Morris-Carter Report are in contemplation. By one of these orders, some 48,000 square miles of territory will be reserved to the natives, this including the most thickly populated areas, in which 86 per cent of the natives are living; while in the second order, 16,000 square miles of the highland area will be assigned to non-natives, one quarter, however, being set aside for a permanent forest reserve. Before these become effective, however, Mr. Ormsby-Gore indicated that it would be necessary to deal with the question of the 'squatters', upon which he confessed frankly that he had not made up his mind. There are now, he pointed out, 150,000 natives in Kenya living on European farms under annual agreement. These hold from the farmer a house and land in return for 180 days labour per annum at a contract rate of pay. There are also other natives in the European area who are not squatters, but in course of time have acquired rights. Some of these have been dealt with already in accordance with the recommendation of the Morris-Carter report, and removed to an agreed location.

THE problem of the squatter is, indeed, difficult. Mr. Ormsby-Gore's dilemma, as he showed, is whether to permit a system to endure, which while it assures a certain amount of labour to the farmer, is open to abuse, as experience has shown, on both sides, or whether to require labour to be obtained from the reserves in conditions which would keep the native in touch with tribal institutions and discipline. In South Africa, where the squatting system has a long history, it is proposed under the new regulations for native lands that it should not further be permitted; while scientific study of native institutions and the effects of the impact of white civilization on native life and morale would favour the stricter regulation of conditions of employment and intercourse, which the restriction of labour to natives from the reserves would make possible. The present mobility of labour in Africa, as recent events have shown, makes it eminently desirable that there should be some uniformity in native policy; and this is, no doubt, one of the considerations which the statesmen of the Union of South Africa have in mind in their expressions of opposition to any interference with present conditions in the mandated territories of South-West Africa and Tanganyika. It was certainly contemplated by Mr. Pirow, the South African Minister of Defence, when, at Nairobi on his way back to South Africa (*The Times*, July 10), he urged the importance of a common policy for native affairs, defence and customs, in the three groups into which he classified British Africa, from Kenya to the Union. A further important step in this direction is also to be noted in the amendments to the constitution of Southern Rhodesia. According to the draft regulations in the White Paper (Cmd. 6218), issued on July 9, the native reserves in future will be vested in a Board of Trustees, and there is to be a Native Department with a Chief Native Commissioner at its head who "in view of his very important responsibilities, may not be removed without the Secretary of State's consent".

Proposed Tribute to Prof. A. L. Bowley

IT is intended to mark the retirement of Prof. A. L. Bowley from the chair of statistics in the University of London by a recognition in some degree commensurate with his distinguished services. Prof. Bowley has not only given to the London School of Economics, since its beginnings in 1895, years of brilliant and devoted teaching; he has at the same time made contributions to social welfare that have been recognized throughout the world, by universities, by learned societies and by Governments. His published writings have given him an eminence all his own, and his kindliness and geniality have endeared him to generations of students and to all who have had the good fortune to work with him. Over the signatures of Lord Kennet, Mr. J. M. Keynes, Prof. D. H. Macgregor, Prof. W. R. Scott and Sir Josiah Stamp, an appeal has been issued, since it is felt that past students and many others will welcome an opportunity to share in an expression of admiration for the work he has done. It is proposed that this tribute of esteem shall include a portrait of Prof. Bowley to be hung in the London School of Economics, and a scholarship or prize tenable in the University of London (at the London School of Economics) to assist a student pursuing undergraduate or postgraduate study in economic or social statistics. Sir William Beveridge has agreed to act as treasurer of the fund, and all subscriptions should be addressed to him at the London School of Economics, Houghton Street, Aldwych, W.C.2, England.

Anglo-German Stork Experiments

THE present experiments on the migration of the stork (*Ciconia alba*) being carried out in England in conjunction with German ornithologists is evidence of the wider possibilities of international co-operation in field ornithology than have hitherto obtained. Earlier in the spring, eleven storks' eggs from German nests were sent to England and placed in heron nests in Surrey by the Haselmere Educational Museum, as the stork is no longer a British nester, and it was hoped the experiment would indicate whether or not the English-born birds under heron foster-parents would follow the same migration route as German birds. However, only one egg hatched, and after a week the stork chick was accidentally crushed to death by the foster parent. It is hoped to repeat this experiment next spring. In June, a further experiment was made when twenty-three nestling storks from East Prussia were distributed to artificial nests in Scotland, Kent and Surrey where they were hand-fed, and it is hoped that if reared, these birds, which are ringed, will shed further light on migration, and how far inheritance plays a part in it.

MUCH work on the migration of storks has been carried out on the Continent in recent years. The early experiments at bird-ringing were made by Brugmann in Holland and Mortensen in Denmark last century with storks (NATURE, Sept. 30, 1933), and later research showed that birds nesting east of the River Elbe used an Asia Minor route to the Natal winter quarters and those nesting west of the river a route through Spain and Morocco. Three years ago, young storks born east of the Elbe were ringed and released west of the river, but soon found their way back. The small percentage of stork rings recovered in Africa has lately been shown to be due to the Egyptian natives treasuring them as tokens for fertility, a barren woman who obtained one having worn it and given birth to children, and hence the superstition spread. Skougaarde has reported a stork ringed in Jutland and believed to have lived between thirty and forty years.

Hadrian's Wall

EXCAVATION of the fort on the Roman Wall at Halton Chesters, near Newcastle-on-Tyne, by the University of Durham Excavation Committee, has made it possible to state definitely for the first time that the building of the wall was completed within a period of five years. A dedicatory tablet on the west gate of the fort has been found, it is stated in a report of the Committee (*The Times*, July 13), which bears the name of Platorius Nepos, the Governor of Britain in A.D. 122–126. As he also directed the first stages of building, the whole erection was completed within his term of office. The excavation has thrown much light not only on the methods of planning and construction of the fort but also on that of the wall itself. It is evident that the original plan was not always followed. For example, the original ditch fronting the wall runs straight through below the existing fort, one of six, which projects 200 ft. north of the wall. The east and west gates of the fort are carried down the entire depth of the filled-in ditch and are built on massive foundations. There is evidence of two considerable reconstructions or enlargements. After the Caledonian invasion, the Emperor Severus rebuilt the fort in about the year A.D. 205, erecting a monumental fore-hall in front of the administrative building. No hall so fine as this, it is stated, has as yet been discovered in Britain, where, in any event, they are rare. It is shown by the foundations to have been 160 ft. long by 30 ft. broad, with a central entrance spanning the north-to-south street. About a century later the fort was increased in size by an enlargement towards the west behind the shelter of the wall. This structure gave the fort the peculiar L-shaped plan which has long been a puzzle to archæologists.

Meteorology for Airmen in India

A COPY has been received of a new publication of the India Meteorological Department (M.O.A. Pamphlet 1936) entitled "Meteorological Organisation for Airmen". The purpose of this pamphlet is made clear in the introductory pages by the Director-General of Observatories, where the relevant part of the organization of the Department is described, together with the procedure to be adopted to obtain weather reports for the different parts of the area with which the Department is concerned ; this area extends from the south-eastern half of the Persian Gulf across the whole of Baluchistan, India and Burma. It is admitted that the existing organization for the supply of weather reports and forecasts for such a vast area falls short of the standards recommended by the International Convention for Air Navigation, particularly in the south of India, the reason being the size of the area in relation to the permitted financial expenditure on the organization, which is less than what it was formerly in spite of the increased demands of aviation, a fact that has necessitated various reductions, including the closing down of the important forecasting office at Quetta.

THE different areas covered by the forecasting centres in India are shown on a key map, which indicates also the centres themselves, the different airship bases, the pilot balloon stations from which information about the winds of the upper atmosphere can be obtained, and the aeronautical wireless stations. More precise information about these centres is given in extensive tables, which, together with further tables giving the various weather codes in use in India, occupy the greater part of the fifty-one pages of the pamphlet. Information of the kind provided is of course practically essential to airmen flying in a part of the world subject to very violent disturbances, ranging from tropical hurricanes to duststorms and tornados and other local phenomena that render aerial navigation dangerous to all classes of aircraft. A form is included, as a detachable page of the pamphlet, to be forwarded to the Director-General by anyone wishing to receive, free of charge, copies of all supplements and new editions as they are issued to cover the inevitable changes and growth of this meteorological service.

Yugoslav Cultural Progress

LITTLE notice is apt to be taken of the quiet constructive work or scientific developments that go on among the smaller nations. With this fact before it, the Society for Promoting Anglo-Saxon Culture in Yugoslavia has commenced the publication of an *Anglo-Yugoslav Review*, a quarterly to be devoted to the furtherance of the use of English among Yugoslavs and also to acquaint the British and American peoples with the educational, cultural and general progress of the South Slav nation. Its appearance coincides with the celebrations arranged for the eightieth birthday of Nicholas Tesla (born on July 10, 1856), which were held at the end of May. Tesla is a Yugoslav by birth, although most of his work and electrical discoveries on alternating and high-frequency currents were made at Paris and in America. A 15,000 horse-power plant of Tesla's conception was erected at Niagara in 1891 to supply power to Buffalo, 25 miles away—a remarkable feat at the time. Indeed, Tesla's fellow-countrymen claim that his work ranks him on a level with Volta, Watt and Faraday. Approximately half the review is devoted to the section on science and invention. Other sections deal with political, economic, sociological and miscellaneous matters, and among these is an account of recent archæological discoveries in Yugoslavia. Among the four British or American contributions is one by Mr. C. H. White, who discusses the cultural consequences when a nation's mineral resources are developed. The review is published in Belgrade, price 10*s*. per annum.

Transmission and Distribution of Electricity

IN a progress report by C. F. Bolton and R. H. Abell on the transmission and distribution of electricity (*J. Inst. Elec. Eng.*, April) there are several points of special interest. The British Grid uses a pressure of 132 kilovolts, but there is a large number of systems operating at 220 kv. in different parts of the world. In Sweden a hydro-electric power station operates over 200 miles at 220 kv. In France there is a line at this pressure which brings hydro-electric power to Paris. Great activity has been shown in electric development in Russia, and the Dnieper system operates at the same pressure. The Boulder Dam project on the Colorado River represents one of the outstanding engineering achievements of recent years. A part of the energy developed, 1·3 million kilowatts, will be transmitted 266 miles to Los Angeles by a 287·5 kv. transmission line. German engineers have constructed several of their 220 kv. lines so that they can be converted ultimately to work at 380 kv. A scheme using a transmission voltage of 400 kv. has been proposed for the establishment of a large water-power station in Norway for supplying power to Sweden, Denmark and Germany. The main transmission system is to be some 650 miles in length. It terminates at Hamburg, and will have intermediate stations at Göteborg and Copenhagen. The generating plant will have a capacity of nearly a million kilowatts (1·34 million horse-power). The British Grid scheme is now completed, and through it, the considerable water-power sources now available in Scotland are being exploited. The problem of 'system stability' arises when large blocks of power are transmitted over long distances. In Great Britain it is not of special significance.

Care of Old Trees

THE general public probably expresses more sentiment upon the beauty of large trees than upon any other aspect of horticulture. Yew trees may, under good conditions, live to the ripe age of a thousand years, and the oak can boast of very considerable longevity. Whilst the life of a tree must sometime come to an end, the artificial conditions of urban England often shorten its span, unless special care be taken. Mr. A. D. C. Le Sueur has recently shown (*J. Roy. Hort. Soc.*, 61, Pt. 4, 149–159, April 1936) what steps may safely be taken to check decay. Wounds should be cut to healthy wood, treated with a light creosote fungicide, and then rendered waterproof with bitumen. Branches should be cut close to the trunk. Cavity wounds usually contain wood already decayed, and should be cleaned drastically before filling with bitumen or concrete. Artificial support may be given with cables or rods, rather than by bands. Faulty soil conditions, such as lack of nutrients, water or air, or bad drainage, frequently retard good tree growth in public parks. The paper gives many details for the treatment of such backward trees, and provides innumerable instances of scientific practice of the greatest interest.

Earthquake Records at De Bilt, Holland

TWENTY-ONE years ago, the first number of the *Seismische Registrierungen in De Bilt* appeared under the editorship of Dr. E. van Everdingen. We have recently received the annual report No. 21 for the year 1933, still issued under the same capable direction. The seismological observatory of De Bilt lies about five miles north-east of Utrecht. In 1904, it contained a pair of Rebeur-Paschwitz pendulums and a Wiechert horizontal seismograph, and, in 1912, a pair of Galitzin horizontal seismographs were installed. In 1933, the same instruments were in action with the addition of a Galitzin vertical seismograph. The bulletin for 1933 contains the records of 450 earthquakes, and it is worthy of notice that, besides the usual details with regard to the times of the principal phases at De Bilt and the estimated positions of the epicentre, the editor should have been able to collect notices of nearly one-third of these earthquakes from the countries in which they were felt.

A Bibliography of Wheat

A BIBLIOGRAPHY of world literature on the genetics and breeding of wheat has been issued by the Institute of Plant Industry, U.S.S.R., and forms the first volume of a new series of publications on wheat (*Bull. App. Bot., Genet. and Plant Breeding*, Series VA, No. 1, pp. 136; 1935). In this work, the titles of articles or books appear in the language of the original contributions, and, where these have been reviewed, reference to the reviewing journal is given. The material is classified under various headings and, within each class, is arranged chronologically. An author index is included.

School Nature Study

THE July number of *School Nature Study* (31, No. 124), the official organ of the School Nature Study Union, contains several articles of interest. An ecological study of the plant life of the salt marshlands of south-west Sussex by A. D. French reveals four important zones, namely, the inner shore banks above high-water mark, beaches and sands above high-water mark, the interzonal region, and the marsh proper. The vegetation of these zones has been carefully examined and recorded. The animal life, too, afforded certain features of interest, and a list of birds is given. The birds of Costa Brava, Spain, have been studied by Margaret M. Hutchinson, and her observations are embodied in a short article (together with a list) in the same number. A. C. Evans, of the Rothamsted Experimental Station, contributes an article on insects and their food. The factors determining an insect's choice of plant food are examined, and the author reveals our great lack of knowledge on this problem, especially from the point of view of plants of economic value. The School Nature Study Union publishes a series of pamphlets dealing with subjects of interest to the biologist, about seventy of which are reprints from *School Nature Study*; five other Special Leaflets are also available. A list of the pamphlets may be obtained from Mr. E. G. Clarke, 7 Stanley Avenue, Wembley, Middlesex.

Library of Conchology

MR. SOHTSU G. KING, the Chinese conchologist and banker, has recently given his valuable collection on conchological literature to the Science Society of China Library, Shanghai. The collection was started some twenty years ago, while he was studying Chinese Mollusca with Prof. A. W. Grabau of the University of Peking. Under their joint authorship, a book entitled "Shells of Peitaiho" was published and is now in its second edition, besides many other scientific papers. The collection consists of many valuable and rare works and several complete sets of journals. It is no exaggeration to say that the collection is unique in the Far East and invaluable to students of zoology in general and conchology in particular. The Council of the Society has passed a resolution that a special room shall be used to house the collection and shall be labelled, "Sohtsu G. King Library of Conchology". The books have already been arranged, and a complete catalogue is in preparation and will be printed and circulated to research institutions and learned societies interested. In addition to the collection, Mr. King has also given an endowment, the income of which is to be used to provide the collection with the necessary periodical literature.

Records of the American Mercantile Marine

A CO-OPERATIVE project has just been launched by the Smithsonian Institution and the Works Progress Administration of the United States, having the two objects of preserving a set of standard measured drawings of American types of fishing vessels and merchant vessels, to be placed in the Watercraft Collection of the United States National Museum, and of providing work for unemployed naval architects, draughtsmen and boat builders. The work is to be known as the Historic American Merchant Marine Survey, and the information is to be gleaned from builder's models, original drawings and the actual vessels. It is to be hoped these efforts will lead to similar projects elsewhere.

London Health Services

THE Annual Report of the Ministry of Health for the year 1934–35 contains a special detailed review of the public health work carried out in London by the London County Council, the City Corporation and the Metropolitan Borough Councils. In view of the general interest of this review, it has now been issued as a separate publication, with a preface by Sir Kingsley Wood, the Minister of Health ("London Health Services". London: H.M. Stationery Office. 1*s*. net). The publication gives a useful survey of the division of functions among the various sanitary authorities in London, and describes the public health and poor law medical services, the food protection services, port sanitary administration, and welfare of the blind.

Rubber Latex

A REVISED edition of the book "Rubber Latex" by H. P. and W. H. Stevens has just been published by the Rubber Growers' Association, 19 Fenchurch Street, London, E.C.3, and a copy will be sent to any reader interested, on application. It deals in 224 pages with the properties, composition, coagulation, concentration, manipulation and compounding of latex and latex pastes, the vulcanisation of latex and latex products, and dipping and electro-deposition. The final chapter deals with a selected list of nearly a thousand recent British patents, and indicates the growing importance attached to the direct application of latex.

'Loose-Leaf Binders' for NATURE

MESSRS. EASIBIND, LTD., Pilot House, Mallow Street, London, E.C.1, have sent us a specimen 'binder' made to take twenty-six issues of NATURE, without advertisements. The first and last numbers are held by stout wires passing through the centre pages of the issues, and intermediate copies are carried on thin wires which go alternately into one of two parallel slots in a metal fitting at the top and bottom of the back of the 'binder'. By this device

No. 3481 SATURDAY, JULY 18, 1936 Vol. 138

Direction Finding by Sound*

By Dr. W. S. Tucker, O.B.E., Director of Acoustical Research,
Air Defence Experimental Establishment

It is a regrettable fact that some of our scientific activities have required the stimulus of war to initiate them and the fear of war to keep them alive. Not the least striking example of this impingement of military necessity on scientific research is afforded by the subject of direction finding by sound. During the Great War, sound provided the only means of locating the submarine that threatened our shipping, mining operations that threatened our entrenchments, the distant and invisible gun and the aeroplane flying behind cloud or in the darkness; and this search by sound provided four widely differing methods all requiring advanced scientific technique. The subject is so large that I am proposing to confine myself to the operation of finding the direction of sound transmitted through the air.

It is curious that, of air-borne sound, the War provided us with ideal sources—the gun and the aeroplane. The gun report is an almost perfect example of an impulsive sound—the anti-aircraft shell burst is even better. The aeroplane, so complex in the nature of its sound, has something so rich in its elements—high frequency, low frequency, impulsive, musical, non-musical—that it gives a fascinating mixture of qualities taxing the provision of many kinds of apparatus for investigating its properties.

The fear engendered by these characteristic sources—gun and aeroplane—has stimulated lines of scientific inquiry almost entirely dominated by military requirements, and such inquiries and the results of them have fallen into the category of secret investigations with all the handicaps of fettered scientific discussion. I will try, however, to strip my subject as much as possible of its war implications, and endeavour to show how fascinating the study of sound direction finding can become.

All living creatures equipped with listening faculties appear to have a capacity for obtaining the direction of sound, but this sense of direction is only provided by the functioning of two ears. When either a human being or an animal is deprived of hearing in one ear, sense of direction is very seriously impaired. What is called the binaural faculty has to be replaced by that of a single ear, in which reliance must be placed on variations of intensity due to the shadowing of the head. Even so small a creature as the cricket, using two ears, shows good directional perception, as has been shown by the direct flight of the female to the chirping male, and it has been shown that removal of the tympanum of one ear of the female deprives it of this capacity[1]. Some interesting experiments of Engelmann[2], working in the laboratories of Prof. D. Katz, illustrate the performance of a very intelligent sheepdog called "Asti", one of whose ears was bandaged. The dog then lost its remarkable powers of direction finding. Some residual sound in the bandaged ear appeared to give partial help, but, in addition to exhibiting false judgments, the dog's reaction time changed from about ¾ second to a mean of nearly 4 seconds[3].

What, then, is the function of the second ear? The answer appears to be perfectly easy when the sounds to be located are impulsive or of short duration. The ears owe their directive capacity to the fact that they are separated, and the distance between them is a determining factor. If the sound is directly in front, the sound arrives at the two ears simultaneously; if from the side, one ear receives the sound a very short time earlier than the other, the measure of that time being determined by the angle that direction makes with the median plane of the head, or with the line perpendicular to that joining the ears. From the known speed of travel of sound and the distance between the two ears, a time interval can be worked out for every direction, so that, if the brain recognises this time interval, a definite direction can be associated with it. A more accurate appreciation of direction can be given by turning the head until we face the sound, and this corresponds to the simultaneous arrival of the sound at the two ears. This time difference theory, enunciated by Hornbostel[3], has been supported by most modern exponents, and has been shown to be not inconsistent with the late Lord Rayleigh's theory of location by phase difference.

---

* From the Friday evening discourse at the Royal Institution delivered on May 1. The author wishes to acknowledge with thanks his indebtedness to the Royal Engineer Board of the War Office for permission to refer to matters of military interest.

A very good example of direction finding by measuring time intervals is shown in sound ranging of guns[4]. Here the ears are replaced by microphones. Instead of the base length of only about 6 inches for the two human ears, the microphones were at the ends of a base from half-a-mile to three-quarters-of-a-mile long. The time intervals were therefore long and measurable by suitable timing apparatus, and from these any two microphones gave a direction, three gave two directions and an intersection, and therefore a location. Three more microphones were used in an installation, in the War, making six in all, giving five directions and a mean of locations which improved the accuracy of location very considerably.

The unit of measurable time difference was then about 1/100 sec., and recent advances in sound ranging have made it possible to measure to less than 1/1000 sec.; but the human mechanism of time recording is very much finer than this. Thus, experiments have shown that the pair of human ears with the interpretation of the brain can distinguish time intervals of 30/1,000,000 sec., and interpret them into a perceptible difference in direction. Animals can do even better than this. I am indebted to Prof. Katz for communicating to me some results obtained in his laboratories at the University of Rostock by Engelmann[5]. Engelmann's method of testing the faculties of animals exhibits great ingenuity. Two similar screens placed side by side served to hide a source of sound, and, on a hook behind the screen hiding the source, was placed a piece of sausage. A dog was trained to associate the correct choice of the screen with the reward of a piece of sausage. By adjustment of the screens both as regards distance from the dog and of their distance apart, the limitations of the dog in the correct identification of the screen gave a measure of the angular separation of the screens, and hence the capacity of the dog to separate directions of sound. The experiments were carried out with three dogs, the dog "Asti" giving the remarkable performance of a separation 2°9′, corresponding to a time interval of 14/1,000,000 sec. A smaller dog, "Fritz", gave even better results: a separation of 1°16′ and time interval of 7/1,000,000 sec.

Experiments with cats, in which the source of sound was the rustle of two white mice in a cage, gave, in one case, a separation of only 48′ and a time interval of 2·8/1,000,000 sec. Experiments with hens and chickens gave other figures showing how very sensitive to sound direction for certain sound these creatures are. Here the source of sound which served as a test for the hen was the 'cheep' of the chick, and the chicken was tested on the cluck of the mother hen.

The following table shows the relative capacities of the various creatures as regards accuracy of direction finding; man is obviously outclassed.

Subject	Base-length between ears	Accuracy of direction finding	Distinguishable time intervals between the ears
			(10^{-6} sec.)
Man	14 cm	4°18′	30
Dog:			
"Asti"	18 cm.	2° 9′	14
"Fritz"	9 cm.	1°26′	7
Cat	7 cm.	48′	2·8
Hen	3 cm.	2° 9′	3 3
Chicken	1·5 cm.	2° 9′	1·6

I have emphasized so far the time difference explanation of this phenomenon of directional listening; but it may be objected that the direction finding of a continuous sound like an aeroplane cannot be so accounted for, since we would appear to have no discrete pulses on which we can observe such time difference. I have already referred to the quality of aircraft sounds and have mentioned its partly impulsive character. However much help may be derived from what is called the phase difference between the waves of incoming sound, our experience with troops has taught us that it is these flutterings and pulses which appear to be given out irregularly that make direction finding easy. Even when the source of sound is entirely musical, atmospheric irregularities make the sound appear to fluctuate, and it is the time interval between the arrivals of these discrete fluctuations or flutterings which give the binaural sensation so prominently.

Now it must be admitted that this faculty of direction finding by sound grew naturally, both in men and animals, from the necessity of locating sounds nearly in the horizontal plane. With the advent of the aeroplane, we are faced with the necessity of listening to overhead sounds also, and here our listening mechanism shows a lack which it is probable Nature will never contrive to redress. When listening to the overhead sound, rotation of the head does not alter that time difference between the arrivals of the sound at the two ears upon which we depend for acquiring sense of direction, and this disability, although greatest in the overhead position, still persists, though in a gradually lessening degree, as the angle of elevation of the aeroplane is reduced. To get accuracies in the overhead position comparable with that of horizontal listening, the listener must make the axis of his body horizontal, that is, he must lie down with his length parallel to the course of the aeroplane before making use of his ears for direction finding. His head is then placed as well for locating the overhead sound as previously, when the body was erect, it was placed for locating sounds on the ground.

It may be that this uncertainty in placing an aeroplane which is overhead is responsible for the feeling experienced during the War that the bombing aeroplane seemed to spend an undue amount of time exactly over us, an impression, no doubt, which added to the terror of this overhead menace.

In the design of an efficient sound locator there is one obvious improvement to aid directional listening, namely, the artificial separation of the two ears. If we can, so to speak, pull the ears out of the head and separate them, we can increase for any given direction that time difference upon which a sense of direction depends. This pulling out of the ears can be done artificially by means of tubes placed in the ears with their open ends widely separated. If, further, the terminations of these tubes can be some type of sound collector, such as a horn, the improved directional properties can be supplemented by a magnification of the sound.

This was the fundamental principle which led to the design of the first British sound-locator, produced by the Anti-Aircraft Experimental Section of the Munitions Inventions Department under Prof. A. V. Hill. Four wooden horns were used on altazimuth mounting. The operation of direction finding involves two pairs of ears and two pairs of trumpets. The azimuth listener uses the horizontal pair which rotates about a vertical axis, while the altitude pair rotates about a horizontal axis. In operation, all the trumpets in a frame move together so that their mouths always point in the same direction.

It must be noted also that the azimuth listener must be on the correct bearing before the altitude listener can function correctly. This second pair of trumpets takes the place of hypothetical ears mounted on the crown of the head and under the chin, and the corresponding directional listening operation would be analogous to the nodding of the head after it has been swung round to face the sound.

In 1923, the Acoustical Section of the Air Defence Experimental Establishment had the problem of producing a portable sound locator which could be packed in a case after dismantling. The base length of 4 ft. 6 in. was used, but the horns were made smaller than in the early British pattern and, being metal-lined, withstood damage, for a fine crack in a wooden horn of the early type kills its magnifying properties. The performance of this locator after training was adequate for the slow moving and heavy bombing aircraft of ten years ago, but, owing to the high speed of modern aircraft, it is gradually losing its usefulness.

This magnification produced by horns is helpful because it reduces the reaction time of the listener ; hence he gets on the correct bearing more quickly than if he were dealing with faint sounds. The horns, however, have another property which helps the listener. As they are rotated into the true direction, the intensity increases, and the listener will naturally turn the horn so that the sound is loudest. High-pitched sounds are more strongly magnified than the low-pitched sounds. The intensity variation as the horn rotates is also greater for the high-pitched sounds. We do not hear the aeroplane through the horns exactly as we hear it with the unaided ear, and, as we rotate them, the quality of sound changes, being richest when the horns face the sound.

We get, then, three factors affecting our correct estimate of direction—the binaural sense which depends on time difference, giving us the sense of sound straight ahead when facing it, the intensity of the sound which becomes greater, and the quality of the sound which becomes richer and more closely resembles that of the aeroplane as heard by the unaided ear.

Of recent years, several well-known armament firms have produced sound locators in which great diversity of design has been exhibited. Sound collectors have been either of the horn type or have employed concave reflectors with special devices for conveying the sound to the ears. A modern example of the horn type is that produced by Sperry in the United States. Another type, produced by the firm of Barbier, Benard and Turenne, provides collectors each one of which is composed of a number of horns connected at their narrow ends. The Sautter Harlé locator, also produced in France, is of the reflector type, and so also is one produced by the firm of Goerz of Vienna, in which many striking acoustical features are introduced.

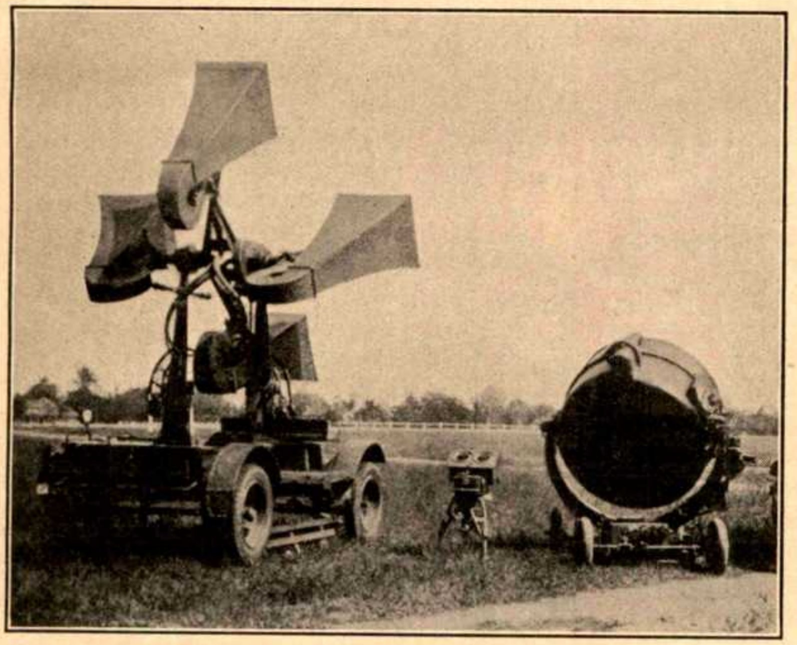

FIG. 1. THE SPERRY SOUND LOCATOR.

The Sperry sound locator (Fig. 1) consists of large exponential horns, that is horns with curved sides in which the cross-section diminishes in logarithmic relation with distance from the mouth. As such they accord with the latest scientific principles and, in fact, lend themselves to calculation both as regards frequency response and frequency range. They are 16 ft. long and give a base length of 7 ft. The listeners are, as it were, clamped to the horns by caps carrying earpads through which sound has access to the ear. They give an impressive magnification, but, unfortunately, are extremely resonant and, in even light winds, provide a disturbing background which hampers listening. This difficulty is overcome by a prolonged period of training. A feature of the trumpet which is liable to be overlooked is the danger to the listener of local gun sounds in which the gun blast is greatly concentrated. These Sperry locators, in the hands of trained troops, give a good performance.

By the way of comparison, the latest British sound-locator is shown (Fig. 2). Collectors which are paraboloid reflectors have been evolved as the result of researches in which the acoustical properties are accurately known. As in the best of the Continental locators, the instrument is trailer-mounted and the listeners adjust the positions of the locator and themselves by hand-wheel control. The instrument is highly directional, is free from trumpet resonance and can be used in moderately noisy surroundings.

In general, a condition of absolute silence is imposed in the neighbourhood of these locators while they are in operation, but with the new English locator it is quite possible to do effective work when onlookers are talking near it, so long as they keep away from the direction of listening.

Reviewing all these types of locator, it is interesting to note that, working on independent lines, the mouths of the collectors, which is an important feature of selective directional listening, and the length of the base between collectors, which determines accuracy of location, have achieved about equal dimensions throughout, but it must be confessed that some of the designs do not accord with the simplicity of the functions which they have to carry out.

Efforts of various countries have been concentrated hitherto on the production of sound locators in which the ear is the ultimate criterion. Directive listening is known to require training, and a certain proportion of military and civil personnel are quite incapable of being trained. The British locator has proved itself to be a very rapid training instrument, but with all possible improvements, some listeners are physically incapable of good performance.

More recently, however, attention has been directed to the production of electrical locators in which it is hoped that difficulties of training will, to some extent, be eliminated.

It is only during the last year that microphones in Great Britain have been produced for all-round listening which can be matched as accurately as the ears are matched. The sensitivity of the microphones themselves is inadequate, and they must have amplifiers similar to wireless amplifiers, but of special design. These again must be matched, or they will, of themselves, introduce time errors or, better expressed, phase changes. Also, the power of discrimination of wanted from unwanted sounds, used automatically by the ears of the listener, must find its analogy in some electrical device, and recently we have been able to produce electrical filters which help to cut out the sounds which form an undesired background.

Finally, we should naturally replace the stethoscopes by telephones, which again must be matched, but that leads us back again to the ear with all its inherent difficulties. There is, however, an alternative to the ear in the cathode ray oscillograph, which may be used in a manner suggested by Dr. E. T. Paris. We have two receptors, so to speak, in the two pairs of parallel plates in the oscillograph, and the two microphone circuits may be connected to these so that each microphone effect can be recorded as a corresponding movement of the spot on the screen. Fig. 3 shows diagrammatically the four plates of the oscillograph, in which plates *aa* correspond to microphone *A* and plates *bb* to microphone *B*. The displacements *aa* and *bb* on the screen shown below correspond to their separate movements. These movements which are, of course, oscillatory, give by persistence of vision a straight line for each microphone, but when the two microphones are connected up, we get the well-known Lissajou figure, which would be another straight line equally inclined to the first two if these two microphone responses are in phase. When out of phase, the effect depends on the nature of the sound. If the sound is a pure musical tone, represented by a sine wave form, the intervening out-of-phase conditions are represented by ellipses. If, however, the source of sound is as complex as that of an aircraft, and is built up of many frequencies, the pattern only becomes simple, that is, the straight line above referred to, if all the constituents are in phase, namely, when the microphones are equidistant from the source.

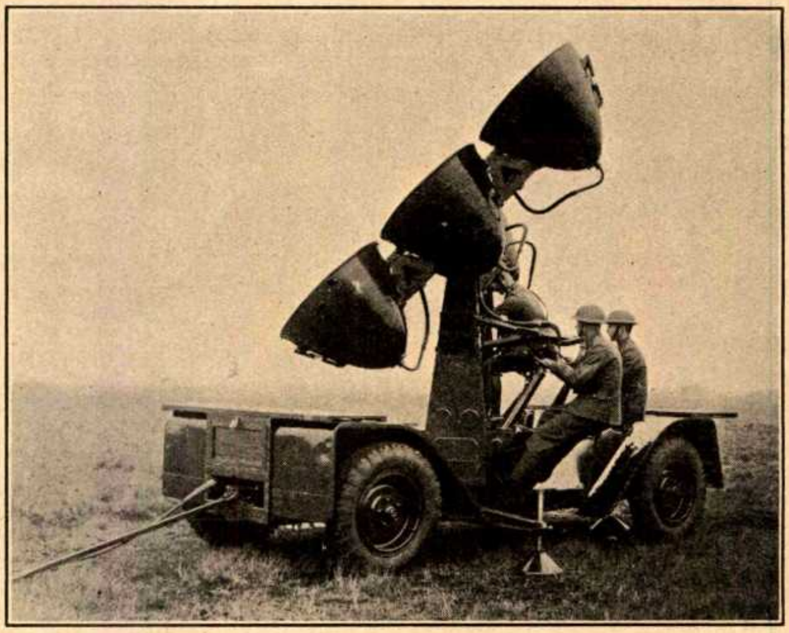

FIG. 2. MODERN BRITISH SOUND LOCATOR.

Gusty winds make directional listening very difficult; for the critical time difference on which direction finding depends becomes variable. The cathode ray oscillograph gives a perfect picture of this disability. The straight line then becomes blurred, and if the sound intensities change, as they do in the two receivers, at unequal rates, the resultant line oscillates. The aural and visual perceptions give an exact parallel. Similarly, other sources of sound, or, it may be reflections of the same source, confuse both aural and visual effects equally. This method of visual indication by the cathode ray oscillograph gives immediate evidence of listening disabilities.

I have so far dealt with sound direction finders in which the two ears or their equivalents in microphones are necessary. There are, however, direction finders in which use is made of single collectors which can rotate to face the sound and so find a maximum of intensity. Although these direction finders are of considerable interest, they fail to give the accuracy shown by the binaural instruments, and, furthermore, present difficulties in recovering the direction of the sound when it is lost.

I will only give one example of this type, which is of interest in so far as it is entirely devoted to peace operations, and deals with the direction finding of fog horns and ships' sirens at sea. The need of supplementing the human ear has been recognized by many navigators, especially as meteorological conditions sometimes baffle the listeners. Situations may also arise when the nearness of the foghorn involves hasty and definite action. The invention of Messrs. W. and T. G. Hodgkinson is directed to the supply of accurate bearings (to half a point of the compass).

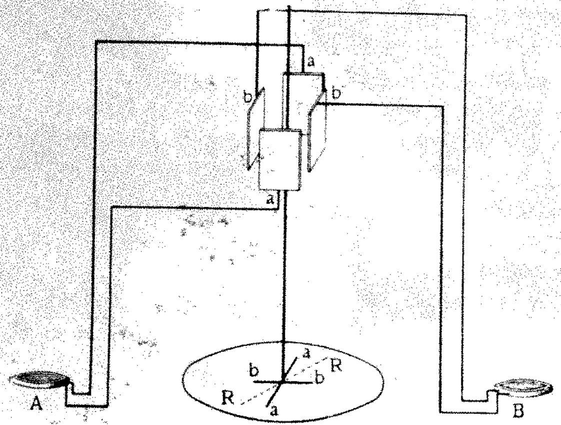

FIG. 3. DIAGRAM OF CATHODE RAY OSCILLOGRAPH.

The devices tried out were of two types. The first and simpler form of direction finder consisted of a paraboloidal receiver mounted in a drum rotatable about a vertical axis. The axis of the paraboloid was horizontal and coincided with a diameter of the drum. At the focus of the paraboloid a contact microphone was mounted, and the mouth of the paraboloid was protected from wind by a perforated screen. Microphone adjustments were such that the noises of the ship on which it was erected and disturbances from wind produced little effect, but it would respond to horns and sirens up to ranges of three miles. The axis of the drum carried a commutator, and brushes were arranged so that, for sixteen positions of the drum, currents generated by sound in the microphone could light a lamp through the agency of a relay. Sixteen of these lamps were arranged in a dial to give the points of the compass against which any sound disturbance could be anticipated. For near foghorns, a group of lights might be shown on a definite arc, the centre of which would give the bearing. This instrument was used for a period on the Mersey pilot-service and on the Holyhead–Dublin mail service. A later pattern, where a much larger drum was used, avoided the operation of rotating the drum, the same effect being achieved by using a number of radial paraboloid receivers, each with its own light indicator. This was installed on S.S. *Victorian* of the Allan Line on the Liverpool–Montreal service. The instrument, though successful, was not brought into general use.

It may be suggested that considerable gain might be achieved by using very large receivers. This development, however, has not been pursued because it has been discovered that appreciable increase in acoustical range has not been comparable—a result which can be attributed to the very high attenuation of sound in the atmosphere. The application of the inverse square law is not helpful in estimating range extension, since, at greater distances than normal listening, the attenuation losses are high in comparison with those due to spherical divergence. Very large receivers have been tried and have resulted in very disappointing performance at long ranges. Thus, large exponential horns which admittedly magnify very impressively, will add only a few miles to the audible range. A gain in accuracy of direction finding may be achieved, but, even so, the accuracy obtained by a single large receiver working on a maximum of intensity cannot compete with that derived by employing the binaural effect, using pairs of receivers of more modest dimensions.

It is obvious that no description of sound direction finding would be adequate without reference to two sources of error. The first one, which applies to the location of all sources of sound, whether fixed or moving, is due to the physical nature of the atmosphere. The effect of wind in creating difficulties of listening range is, of course, familiar, and I do not wish to dwell on this. Meteorological acoustics is a science of itself and might easily occupy the whole of this discourse. It is my purpose rather to indicate in a few words how wind and temperature may affect the direction of listening. We may regard the velocity of sound in still air at uniform temperature as a physical constant, but air is very rarely still and never at a fixed temperature as we ascend. We must increase or decrease the velocity of sound according as the wind is with or against the direction of travel, and according as the temperature increases or decreases. The effect of the variation is to produce refraction, to a greater or less degree, and the effects of these variations have been worked out precisely from mathematical considerations[5]. The following simple illustrations indicate in what manner meteorological conditions affect directional listening. If we consider the wind to increase with height in the direction of listening, the sound ray comes down more steeply. If opposite to the direction of listening, the sound ray is bent so that it comes in at a smaller angle. For example, in a south-west wind so prevalent in England, an aeroplane would be heard in a south-west direction at a higher angle than the true, or, if with the same wind we listen to an aeroplane in the north-east, we should be hearing it at a lower angle. The reason is that wind from the south-west increases as we ascend in nearly all cases.

The effect of the temperature is such that, if no wind had to be allowed for, the aeroplane would always be heard at a lower angle of elevation than it actually is. The reason is that the temperature during the day is nearly always lower as we ascend, and, in consequence, the velocity decreases. The effect is the same as if we were listening against the wind, as described above. At night, however, the reverse effect frequently occurs, because the ground cools by radiation and the temperature of the air above it is higher. At night therefore it frequently happens that we hear an aeroplane at a greater angle of elevation. These effects are quite large, as much as 10° for very low angles of elevation, but when the aeroplane approaches the overhead position, these errors become negligible. An illustration is shown in Fig. 4, where the directions of sound rays given out by an aeroplane at 7,000 ft. are mapped out. This acoustical distribution of rays can be worked out if we know how wind and temperature change as we ascend. Here, the sound rays spread in such a way as to give a region in which no sound is heard, hence no direction can be defined; but above and below it there are errors in direction as shown. Provision for such corrections will eventually be made, for, if sound is to be employed for controlling gun fire, great accuracy will be essential in obtaining direction.

The survey of the atmosphere as regards wind and temperature has been accessory to a large research (now being carried out by P. Rothwell) on the refraction of sound in the atmosphere.

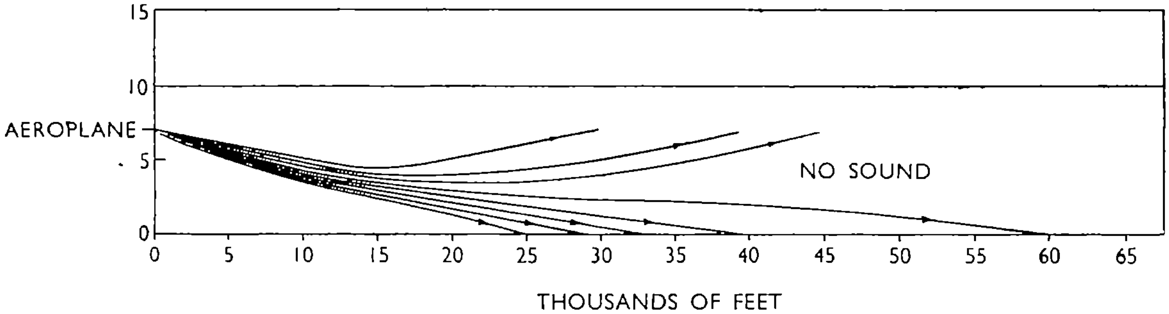

FIG. 4. DIRECTIONS OF SOUND RAYS FROM AN AEROPLANE AT 7,000 FT.

A more serious error in sound direction finding occurs if the source of sound is moving. The small velocity of sound relative to that of light is responsible for an error called the 'lag of sound', and it can be defined as the angle between the line of sight and the direction of listening. Taking an aeroplane as the moving source, while the sound which it gives out is approaching the listener, the aeroplane has travelled on its course, so that the listening direction will always be behind the visual one. The lag of sound varies according to the direction in which we are listening. If the aeroplane is coming straight towards us or receding from us, there is no correction; but if it is flying across our field of vision, such as it would be if vertically overhead, the lag of sound is a maximum. The angle thus becomes approximately $\varphi = \nu/V$ where V is the speed of sound and ν the airspeed of the target, but a wind correction must be incorporated with this if the wind varies between the aeroplane and the ground. No correction is necessary if there is no wind. How large the correction may be is indicated in the accompanying table, which gives the angular lag of listening direction for an aircraft flying overhead. Against this correction, a year is quoted, corresponding roughly to the speeds of aircraft prevalent at that time.

	Air speed : miles per hour	Angular error overhead position
1918	60	4·6°
1926	120	9·1°
1934	180	13 8°
1936	240	18 4°
1940?	300	23 0°

The corrections would suggest a very serious disability in sound locating, but this disability may easily be exaggerated, for, if we know the airspeed of the aircraft and the direction in which it is travelling, corrections may be applied with considerable precision. The various sound locators have devices attached to them which insert the lag of sound corrections and, in some cases, corrections for wind and temperature refraction.

We must, of course, remember that acoustical direction finding cannot compete with the precisions of visual observations, but it is not too much to say that, on fixed sources of sound, an error of ½° can be assured with the modern instruments, and with an aeroplane flying at reasonable heights, all sound locator manufacturers quote 2° accuracy. The distance away of the target is, of course, a determining factor, as with low-flying targets having a high angular velocity, difficulties of following, both physical and psychological, make the operation of direction finding difficult. By careful training, a listening team of two listeners per locator can achieve an accuracy of 1° for a reasonable proportion of the time during which the aircraft is within hearing and at heights above 5,000 ft.

Is sound as an aid to defence likely to be completely outclassed because of its low velocity ? We are apt, with the sensational reports of greater and greater speeds of aircraft, to exaggerate the heavy handicaps from which sound suffers. In direction finding, it is true that a large correction may be involved, but, if it is an accurate one, the result may still be adequate for the purpose for which sound locators were designed. We are by no means approaching yet the stage described in the well-known petrol advertisement, and we have one consolation in the fact that very high-speed aircraft produce much stronger sounds than those flying at lower speeds, so that what we lose in time through high speed we gain in range of audibility.

It is not desired, however, to close on the note of war. We are endowed with a directional listening faculty, the study of which has been seriously neglected. We scarcely appreciated that we had this faculty until sound locators were designed and time differences exaggerated, so that an almost uncanny throwing of our perception of sound from one ear to the other was observed only by a slight rotation of such instruments.

We have claimed the impulsive character of the aircraft sound as a valuable asset in sound direction finding, and we have been able to explain the phenomenon of direction listening on the time difference theory of Hornbostel. It has, however, been the subject of psychological researches to try if sense of direction is lost when the sounds are pure tones. Banister[6] has by suitable laboratory equipment tested certain observers on pure tones and has come to the conclusion that tones of frequency ranging from 133 cycles to 1,705 cycles can give a binaural effect and that discrete impulses are not essential. Our own experience is that lower frequency pure tones are very difficult to locate.

Banister has attempted to reconcile these results with Hornbostel's theory of time differences and has produced a theory which may explain why such an operation is possible. The crests of the sound wave, so to speak, can fulfil the function of discrete pulses, if certain assumptions are made on the mechanism of the ear.

These and other experiments on the theories of hearing should benefit by the attention now being devoted to sound direction finding, and it is hoped that instruments devised specifically to defend us against war dangers will thus give an impetus to work of purely scientific value.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD , ST. ALBANS

the bulkiness of the 'stitched' edges of a pile of loose issues is to some extent minimized. The 'binder' has an attractive dark green imitation leather finish, it is easy to manipulate, and is a convenient means of keeping loose issues together pending binding up a volume, or even permanently. The price of the binder is 3*s.* 6*d.* (4*s.* including postage).

Civil List Pensions

AMONG the Civil List pensions granted on March 12 and recently announced in a White Paper (H.M. Stationery Office, 139, price 1*d.*) are the following pensions for services to science: Miss A. M. Buckton, in recognition of her services to literature and of the services rendered by her father, the late Mr. George B. Buckton, to entomology, £60; Mrs. S. I. Cunningham, in recognition of the services rendered by her husband, the late Mr. J. T. Cunningham, to zoology, £90; Miss R. M. Fleming, in recognition of her services to anthropology and geography, £80; Mrs. C. D. Hodgkinson, in recognition of the services rendered by her husband, the late Prof. W. R. Hodgkinson, to chemistry, £90; Mrs. B. Kaye, in recognition of the services rendered by her husband, the late Mr. W. J. Kaye, to the study of archæology, £60.

Grants for Cancer Research

AT the recent quarterly meeting of the Grand Council of the British Empire Cancer Campaign, grants totalling £5,296 were approved; £1,187 to Dr. A. Pollard, working at the Courtauld Institute of Biochemistry at the Middlesex Hospital, on a special scheme of biochemical research inaugurated by the Scientific Advisory Committee; £150 to Dr. F. G. Spear, working at the Strangeways Research Laboratory, Cambridge, for the purchase of a low-voltage equipment apparatus, and £700 for the purchase of a 200 k.v. 10 m.a. Greinacher set; £300 for six months for work being carried out under the direction of Mr. F. C. Pybus through the North of England Council of the Campaign; £1,256 for fifteen months to Dr. Alexander Haddow, who is transferring from his research appointment in Edinburgh to continue special research work at The Royal Cancer Hospital (Free); £320 to Mr. Nevill Willmer, working at the Physiological Laboratory, Cambridge, for technical assistance and purchase of apparatus; and £150 for six months to Dr. Alice Leigh-Smith, working under the direction of Dr. Thomas Lumsden at the London Hospital.

The Structure of Aneurin and Thiochrome

MESSRS. F. BERGEL and A. R. TODD point out that in their letter under this title in NATURE of July 11 (p. 76), formulæ I and II are printed with HCl apparently attached to carbon atom 5′ of the thiazole nucleus; actually the HCl should be represented merely as attached to the molecule as a whole, since it cannot be allocated with certainty to any particular nitrogen atom; it cannot, of course, be attached to a carbon atom. In formula III a single bond should be inserted between C_5 of the pyrimidine ring and the thiazole nitrogen.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A lecturer in biology in The Polytechnic, Regent Street, London, W.1—The Director of Education (July 20).

A lecturer in mechanical engineering in the Burnley Municipal College—The Director of Education, Education Offices, Burnley (July 20).

An assistant in the Mechanical Engineering Department and an assistant in the Electrical Engineering and Physics Department of the Coventry Technical College—The Director of Education, Council House, Coventry (July 22).

Mechanical engineers for the Supply Board Technical Establishment under the Director of Ordnance Factories—The Under-Secretary of State (C.5), War Office, London, S.W.1 (July 24).

Four instructors in motor engineering in the South-East Essex Technical College—The Clerk to the Governors, Five Elms Council School, Wood Lane, Dagenham (July 24).

A lecturer in mathematics, and three lecturers in engineering, in the Acton Technical College, High Street, Acton, 3—The Principal (July 24).

A lecturer and deputy director of the Department of Anatomy in the St. Thomas's Hospital Medical School, London, S.E.1—The Dean (July 24).

An assistant lecturer in physics in the University of Manchester—The Registrar (July 29).

A lecturer (Grade IIb) in electrical engineering in the University of Birmingham—The Secretary (July 29).

Junior scientific officers in the Directorate of Scientific Research of the Air Ministry—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (July 31).

A head of the Department of Mechanical Engineering in the Bradford Technical College—The Principal (July 31).

A civilian scientific officer in the Admiralty Scientific Pool—The Secretary of the Admiralty (C.E. Branch), Whitehall, S.W.1 (July 31) (quote C.E. 3709/36).

A demonstrator in chemistry in the University of Aberdeen—The Secretary (August 8).

A temporary assistant lecturer in chemistry in the University of Manchester—The Registrar (August 8).

Two part-time demonstrators in inorganic chemistry in the University of Leeds—The Registrar (August 15).

A lecturer in fuel technology in the University of Sheffield—The Registrar (August 15).

A lecturer in metal mining in the University of Birmingham—The Secretary (August 15).

A University reader in physiology in the London Hospital Medical College—The Academic Registrar, University of London, S.W.7 (September 11).

A part-time lecturer in science in St. Paul's Training College, Selly Park, Birmingham—The Principal.

A part-time demonstrator in mathematics in University College, Southampton—The Registrar.

An assistant lecturer in geography in University College, Hull—The Registrar.

Atomic Masses of Uranium and Thorium

WITH ions from a spark between a thorium or uranium electrode and a tin electrode, it was found that easily resolved doublets are given by the mass-spectrograph, formed by the doubly charged thorium ions with the tin isotope at 116 in one case, and in the case of uranium with the isotope at 119 (Fig. 1). The mass difference is found to be 0·120 ± 0·003 for thorium (the average of six doublets of nearly equal intensity), and 0·131 ± 0·003 in the case of uranium (average of the values for the five best doublets). The packing fraction for the tin isotopes has been determined by Dr. Aston[1] as 7·3 ± 1. Using this value, the atomic mass of thorium (oxygen = 16·000) is 232·070 and that of uranium 238·088.

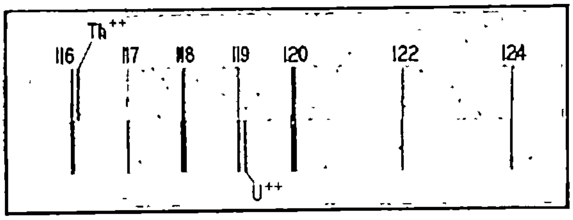

FIG. 1. Ions from electrons of tin and thorium (above) and tin and uranium (below).

Doubly charged ions of the faint isotope of uranium[2] at 235 appeared on four photographs, unsymmetrically spaced between the tin lines at 117 and 118. Its mass was found to be 235·084 ± 0·01. The proportion of this isotope is 0·4 per cent, according to the actino-uranium theory. Reduced to the chemical scale, the atomic weights become 232·024 for thorium and 238·028 for the mean of the two uranium isotopes, as compared with the usually accepted values 232·12 and 238·14. The discrepancy of approximately one tenth of a unit is too large to be ascribed to an error in the masses of the tin isotopes.

From their analysis of the transformations induced by neutron bombardment of uranium, O. Hahn, L. Meitner and F. Strassmann[3] have recently concluded that a uranium isotope of mass 235 exists with a half-life of only 24 minutes. It is transformed by β-ray emission into eka-rhenium ($N = 93$) of the same mass, which is probably a long-lived product. As the uranium and pitch-blende samples used in the present experiments were of unknown origin, analyses of the uranium ions from purified samples of uranium salts were made to make sure that the faint component is an isotope of uranium and not by any chance eka-rhenium. Pure uranyl nitrate crystals were heated and packed in a nickel tube. With this electrode the isotope at 235 was observed apparently in the same ratio as with the other electrodes. No precipitate was obtained by hydrogen sulphide, showing the absence of an appreciable amount of eka-rhenium. The uranium was next freed from other elements by precipitating it as sodium uranyl acetate. This salt when heated and used as the electrode also gave the isotope at 235 just as before. Since this long-lived isotope at 235 thus belongs to uranium, the short-lived isotope formed by neutron bombardment must be isomeric with it, the two having the same mass and charge but differing in nuclear properties.

Unimolecular Elimination and the Significance of the Electrical Conduction, Racemization and Halogen Replacement of Organic Halides in Solution

THERE are a number of cases in which the development of electrical conductivity in sulphur dioxide solution has been held to indicate the electrolytic dissociation of an alkyl halide. One of the best known examples is that of *tert.*-butyl iodide[1]. We find, however, that *tert.*-butyl chloride absorbs bromine quantitatively in sulphur dioxide, the products being *iso*butylene dibromide and hydrogen chloride. This suggests a rather rapidly established equilibrium,

$$\mathrm{Me_3CCl \rightleftarrows Me_2C : CH_2 + HCl},$$

in which, however, the left-hand components have the smaller free energy. α-Phenylethyl chloride also is said to give a conducting solution in sulphur dioxide: we find that the pure chloride in the pure solvent does not conduct, but that when there is conduction, styrene and hydrogen chloride are present:

$$\mathrm{CHPhMeCl \rightleftarrows CHPh : CH_2 + HCl}.$$

Under conditions of purity in which the chloride does not conduct, hydrogen chloride itself has negligible conductivity in small concentration, but even in these circumstances the addition of bromine leads to a quantitative yield of styrene dibromide.

Observations of the unimolecular racemization of optically active alkyl halides have also been held to measure their rates of electrolytic dissociation or at least their ionization. α-Phenylethyl chloride has been shown to racemize in sulphur dioxide at a rate which is unaffected by added chloride ions[2]. A similar but more rapid racemization has been observed with formic acid as solvent[3]. In formic acid also styrene and hydrogen chloride are formed; we find, moreover, that the rate of racemization is substantially accounted for by the rate of formation of hydrogen chloride. In sulphur dioxide a direct comparison of rates is scarcely possible owing to the one-sidedness of the equilibrium.

The unimolecular replacement in sulphur dioxide[4],

$$\mathrm{CHPhMeCl} + \mathrm{I}^- = \mathrm{CHPhMeI} + \mathrm{Cl}^-,$$

is open to the same explanation, since styrene adds hydrogen iodide, which would be formed from the added iodide ions and the liberated hydrogen chloride. Several supposed rearrangements can be similarly re-interpreted.

We are thus able to group all these conductometric, polarimetric, kinetic and other observations under our general mechanism (customarily labelled *E*1) for unimolecular elimination reactions :

$$\left.\begin{array}{lll} >\mathrm{CH.CR_2.X} & \xrightarrow[\text{slow}]{} & >\mathrm{CH.}\overset{+}{\mathrm{C}}\mathrm{R_2} + \overset{-}{\mathrm{X}} \\ >\mathrm{CH.}\overset{+}{\mathrm{C}}\mathrm{R_2} & \xrightarrow[\text{fast}]{} & >\mathrm{C:CR_2} + \overset{+}{\mathrm{H}} \end{array}\right\} \quad . \ . \ (E1)$$

This mechanism assumes that the rate-determining stage is the ionization of the halide, and to this extent we support the inference drawn by previous investigators[2,3] to the effect that ionization is fundamentally involved. In our mechanism the instability of an alkyl cation containing a potential proton is made responsible for the production of olefin.

Experimental particulars and more extended applications of the *E*1 mechanism will be published in the *Journal of the Chemical Society*.

Equilibria in Salt Systems with Deuterium Water

IN connexion with the letters of Bell[1], of Partington and Stratton[2] and with editorial notes[3], it is of interest to note the degree of activity in this field. As is justly stated in the second letter cited above, "measurements of dissociation pressures of salt hydrates are somewhat difficult". By way of illustration, whereas Perpérot and Schacherl[4] report a value for the dissociation pressure equilibrium at 25° of cupric sulphate penta- and tri-deuterates which is 36 per cent lower than the corresponding value for the ordinary hydrates, two of us in 1934 had found this pressure difference to be only 8 per cent. We shall therefore welcome the promised results of Partington and Stratton. We have studied pressure equilibria in this and other univariant salt deuterate systems with and without the liquid phase (saturated solution) present, over a range of temperature.

The solubility relations of salts in deuterium water seem to have received less attention[5]. A few results may perhaps be of interest. If, following "International Critical Tables", concentration is stated in terms of moles of anhydrous solute per 1,000 gm. (55·51 moles H_2O) in the case of ordinary water, for purposes of comparison we may state the number of moles of solute per 1111·7 gm. (55·51 moles D_2O) in the case of deuterium water. For potassium chloride on this basis, we find the solubility in deuterium water lower than that in ordinary water by about 7 per cent at 30°, 3·6 per cent at 100°, and 1·5 per cent at 180°.

In speaking of the solubility of deuterates and hydrates, we refer to solubilities in deuterium water and in ordinary water respectively. Cupric sulphate pentadeuterate is, at 10°, nearly 12 per cent less soluble than pentahydrate; but the difference in solubility falls to about 1·5 per cent near 96°, which is close to the transition temperatures of both salts to their tri-aquo forms. Strontium chloride hexahydrate passes to dihydrate at 61·3°, and the hexadeuterate to dideuterate about 56·5°. The graph of solubility of hexadeuterate against temperature lies lower in concentration than that of the hexahydrate at lower temperatures but crosses the hexahydrate curve about 10°; the dideuterate solubility curve crosses the hexahydrate curve about 60° and the dihydrate curve about 115°, both deuterate curves showing a faster change of solubility with temperature than the corresponding hydrate curves.

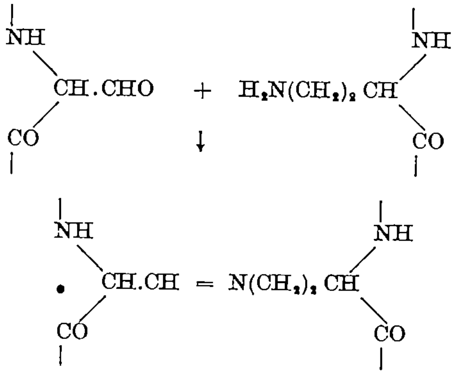
Cross-Linkage Formation in Keratins

THE depilation of hides and skins prior to tannage[1], and the permanent setting of stretched hair and wool[2] are both important industrial processes considered to be governed by the development of resistant cross-linkages between the peptide chains of keratins. Speakman[2] has suggested that when stretched wool fibres are set in steam, the cross-linkages developed consist of –S–NH– groupings formed subsequent to the hydrolysis ($\mathrm{R.S.S.R.} \rightleftharpoons \mathrm{R.SH} + \mathrm{HOS.R}$) of the cystine disulphide cross-linkages; but it is admitted that other resistant linkages must be formed when cross-linking is attended by loss of sulphur.

A possible chemical mechanism, hitherto overlooked, for the production of such resistant linkages may arise by the auto-oxidation-reduction of the sulphenic acid side-chains produced by the hydrolysis of the cystine disulphide cross-linkages. Such decomposition of the sulphenic acid side-chains would yield hydrogen sulphide, and aldehyde groups ($>\mathrm{CH.CH_2.SOH} \rightarrow >\mathrm{CH.CHO} + \mathrm{H_2S}$) capable of linking-up with the amino-groups of adjacent peptide chains, for example, those of lysine.



That the sulphenic acid radical can decompose in this manner is indicated by the production, with the liberation of hydrogen sulphide, of glyoxylic acid from dithiodiglycollic acid, and of phenylglyoxylic acid from dithiodiphenylglyoxylic acid[3]. Keratin is also known to evolve hydrogen sulphide under the action of steam, and to lose 50 per cent of its sulphur when treated with sodium hydroxide[4].

On the assumption that the cystine disulphide cross-linkages must be severed before hair can be removed rapidly from hides, the above hypothesis explains why fresh lime liquors are not efficient depilators, unless they contain reducing agents, for example, sodium sulphide. These substances reduce the sulphenic acid side-chains to cysteine side-chains and thus prevent the generation of aldehyde groups. The unexpected ability of aliphatic primary amines[5] (especially methylamine) to facilitate depilation by fresh lime liquors (free from reducing agents) may also be due to the prevention of cross-linking, since these amines could condense with, and mask, the aldehyde groups arising by the sulphenic acid decomposition.

Association and Dissociation Reactions of Thyroglobulin

FROM their ultracentrifugal studies on thyroglobulin, Heidelberger and Pedersen[1] found that solutions of this protein within its *p*H stability region[2] are fairly homogeneous (Fig. 1). The sedimentation picture shows, in addition to a predominating component consisting of molecules having a molecular weight of about 700,000, a small amount of heavier and lighter molecules with poorly defined sedimentation boundaries. These molecules were assumed to have been formed respectively by the dissociation and association of the molecules comprising the predominating component. It was noticed that on dilution the number of lower molecular weight molecules increased.

In the study of the stability of thyroglobulin being carried out by means of the ultracentrifuge, I have been able to confirm the previous work. I find, however, that this protein dissociates in dilute solutions provided a number of other conditions are fulfilled. Furthermore, I find that the same factors are concerned in the association of thyroglobulin into molecules of higher molecular weight. Finally, I conclude that the number and size of molecules present in a given solution of thyroglobulin may be defined by the following set of variables: protein concentration, salt concentration, temperature, dielectric constant, *p*H and the time the solution has been standing under a given set of conditions.

Those conditions which favour the dissociation of thyroglobulin are as follows: low protein concentration, low salt concentration, elevated temperature, high dielectric constant (glycine and urea were added to the thyroglobulin solutions in this set of experiments), a *p*H displaced from the isoelectric point (only values on the alkaline side, but still within its *p*H stability region, have been studied). These are the same conditions which favour the ionization of the protein.

On the other hand, those conditions which favour the association of thyroglobulin are the opposite or the same as those which minimize the ionization of the protein.

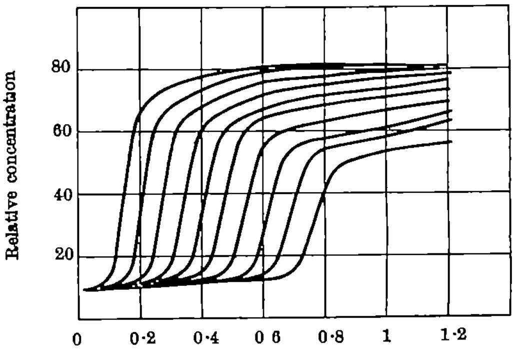

FIG. 1. Sedimentation diagram of thyroglobulin prepared essentially to reference 3.

When placed under the proper combination of conditions, thyroglobulin dissociates with a slow and measurable rate into a series of components of lower molecular weight having well-defined sedimentation boundaries (Fig. 2). I have been able to reverse the reaction, resynthesising the original molecule from the dissociated fragments. Moreover, under the proper conditions, thyroglobulin will associate in due course into higher molecular weight components having definite sedimentation boundaries.

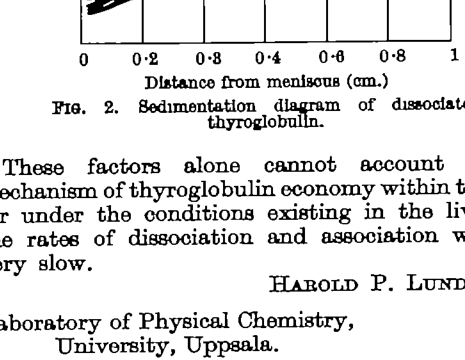

FIG. 2. Sedimentation diagram of dissociated thyroglobulin.

These factors alone cannot account for the mechanism of thyroglobulin economy within the body, for under the conditions existing in the living cell the rates of dissociation and association would be very slow.

Raman Spectrum of Cyclopropane

THE Raman spectrum of cyclopropane is of great interest in view of the fact that it is the simplest of the cyclic hydrocarbons, and also from the point of view of the structure of the cyclopropane molecule. I have investigated this substance both in the liquid and vapour states and have obtained the following results:

Liquid	$\Delta\nu$ (cm.$^{-1}$)	736*	863	1185	1434	1503*	2852*	2952*	3010	3028	3080
	Int.	0*bd*	8*b*	15	2*b*	0*s*	½	1	10	10	6*bd*
	ϱ	*D*	*D*	*P*	*D*	*P*	*P*	*P*	*P*	*P*	*D*
Vapour	$\Delta\nu$ (cm.$^{-1}$)		863	1185					3010	3028	
	Int.		0*b*	2*s*					1*s*	2*s*	

b = broad; *d* = diffuse; *s* = sharp; *P* = polarised ($\varrho \ll 6/7$)
D = depolarised ($\varrho \approx 6/7$).

The frequencies marked with an asterisk in the case of the liquid have not been noticed by the previous investigators[1,2] and are reported here for the first time. The strongly polarised Raman line at 1185 cm.$^{-1}$ and the depolarised Raman line at 863 cm.$^{-1}$ presumably represent the totally symmetric and the deformation vibrations respectively of the triangular carbon ring which forms the nucleus of the cyclopropane molecule. However, for an equilateral triangular model, the doubly degenerate deformation frequency is forbidden in the Raman effect according to Placzek's selection rules. The fact that the Raman line at 863 cm.$^{-1}$ persists even in the vapour state clearly shows that its appearance in the liquid spectrum cannot be due to the influence of the neighbouring molecules. The influence of the hydrogen atoms on the vibrations of the carbon ring might be a possible explanation for the appearance of this line. The matter, however, requires mathematical investigation.

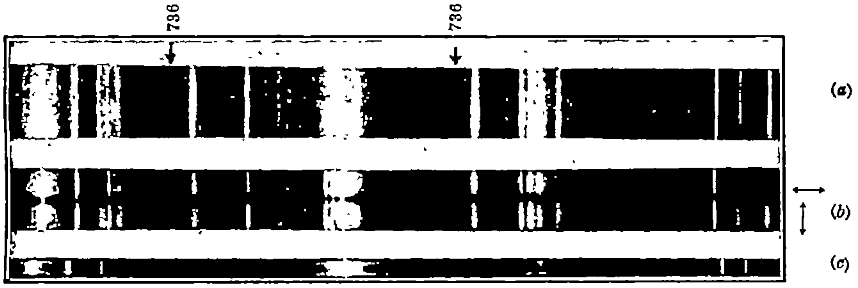

FIG. 1. Raman spectrum of cyclopropane; *a*, liquid; *b*, liquid (polarisation); *c*, vapour.

A striking difference between the liquid and the vapour spectra is noticed when we compare the Raman lines at 3010 cm.$^{-1}$ and 3028 cm.$^{-1}$. In the liquid picture, these two lines are of equal intensity or perhaps $\Delta\nu = 3010$ cm.$^{-1}$ is slightly more intense than $\Delta\nu = 3028$ cm.$^{-1}$. The intensity of either of these is less than that of the Raman line at 1185 cm.$^{-1}$. In the vapour picture $\Delta\nu = 3010$ cm.$^{-1}$ is found to have become considerably weaker, while $\Delta\nu = 3028$ cm.$^{-1}$ has gained in intensity and is almost as strong as Raman line 1185 cm.$^{-1}$ Such a strong difference between the relative intensities of the Raman lines between vapour and liquid in the case of a non-polar molecule is remarkable, and evidently requires further elucidation.

Electronic Specific Heat in Palladium

KEESOM and Clark[1] have shown that the atomic heat of nickel at low temperatures contains a linear term 0·0019 T, which is many times bigger than the contribution from the free electrons to be expected from the Sommerfeld theory. Mott[2] has suggested that this term is due to the unfilled quantum states (positive holes) in the d-shell of nickel, and that a similar term should occur for the other transition metals, whether ferromagnetic or paramagnetic.

In order to test this theory and to make more quantitative data available on the subject, the specific heat of palladium was determined, palladium being chosen on account of its similarity to nickel and its high paramagnetism, which according to Mott should imply a large electronic specific heat. Though the electronic component in these transition metals is larger than usual, it is nevertheless small in absolute magnitude. But since it varies proportionally with the temperature, whereas the specific heat due to the lattice vibrations varies near the absolute zero with the cube of the temperature, the two become comparable in magnitude at sufficiently low temperatures[3]. Experiments were therefore carried out in the liquid helium region.

The specific heat of a block of metallic palladium (weighing 25 gm.) kindly put at our disposal by Prof. Mott was measured between 2·5° K. and 22° K. in a vacuum calorimeter enclosed in a helium liquefier using the Simon expansion method. The sample was contained in a small copper calorimeter on which were wound heating and thermometer coils of eureka wire, thermal contact between the calorimeter and the palladium being effected by the use of helium gas at a low pressure.

The results showed that the atomic heat of palladium in the region 2·5°–22° K. could be expressed in the form

$$C = 0{\cdot}0000224\ T^3 + 0{\cdot}0031\ T \text{ cal./degree.}$$

The first term represents the component due to the lattice vibrations and corresponds to a Debye characteristic temperature of $\theta = 275°$, while the second term represents the specific heat of the free electrons or positive holes. At 2·5° K. the linear term is about twenty times as great as the T^3 term, while the two terms become of equal magnitude at about 12° K. The value of the electronic specific heat is, as predicted by Mott, much higher than for normal metals, and is even greater than that of nickel. The above result is considered from the theoretical point of view in a book on metals by N. F. Mott and H. Jones, to appear shortly.

I should like to thank Prof. F. Simon and Dr. N. Kürti for their advice and assistance in carrying out this determination.

Transparency of Sodium and Potassium Films in the Schumann Region

THE remarkable transparency of alkali metal films reported by R. W. Wood[1] is of considerable interest, on one hand in relation to the theory of electrons in metals and on the other in relation to spectroscopic technique, for these films are unique as filters[2].

We have recently succeeded in depositing transparent films of sodium and potassium on fluorite cooled to liquid air temperature before the slit of a vacuum spectrograph. Photographs of the spectrum of the transmitted light establish that not only does sodium transmit from 2100 A. to 1860 A., as observed by Wood, but also that it transmits through the entire Schumann region to 1250 A. (limit of fluorite). Experiments made with different film thicknesses indicate that there is some absorption in the neighbourhood of 1250–1400 A., and it seems reasonable to anticipate that the transparency of sodium does not extend very far beyond 10 volts. For potassium films (which transmit wave-lengths less than 3150 A.) there is no observable transmission beyond 1400 A., while there is evidence of weak absorption extending to between 1700 A. and 1800 A. Examples of the spectra are shown in Fig. 1.

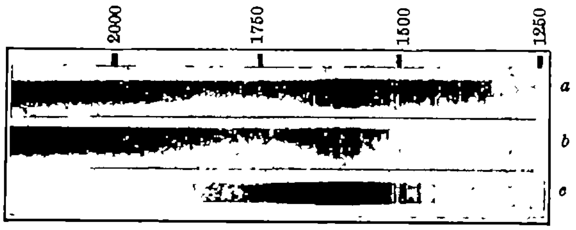

FIG. 1. Transmission of fluorite (*a*) without metal film, (*b*) with potassium film, (*c*) with sodium film.

A sodium film on fluorite is therefore an ideal filter to remove all visible and ultra-violet light of wave-length greater than 2100 A. and to pass the entire Schumann region. A full account of our experiments will be published later, but it is appropriate now to indicate the conflict of the experimental results with the existing theory of the optical properties of metals[3]. According to Wilson's formulæ,

(i) for body-centred cubic lattices the absorption bands overlap and there is no transparency;

(ii) there is a *sharp* rise in the absorption at the low frequency end of an absorption band and slow decrease at the high frequency end.

Both of these conclusions are at variance with the experiments, so the theory cannot be applied in its present form to describe the optical properties of the alkali metals, which ought to afford the most favourable case for the quasi-free-electron model.

One of us (D. G. H.) is indebted to the National Research Council of Canada for scholarships to carry out this work.

High Potassium Diet and the Survival of Adrenalectomized Rats

WHILE investigating the factors influencing the length of survival of rats after adrenalectomy, we found[1] that rats receiving liberal quantities of bread as a supplement to their usual diet lived many times longer than the controls fed on the stock ration alone. That this was only partly due to the high sodium chloride content of the bread (8 per cent by dry weight) seemed evident from the still markedly prolonged survival of rats receiving bread with a sodium chloride content as low as the stock diet, namely, 1 per cent. This diet, containing cereals, meat, molasses and vitamins (Purina Dog Chow), was taken well by unoperated animals. After adrenalectomy, however, the rats soon manifested an almost complete anorexia for the Purina, but those with access to bread in addition ate this well almost until the time of death. Consequently, these animals ingested more sodium chloride and a greater number of calories than the rats on Purina alone—facts favouring survival.

In explanation of the preference shown by the rats for bread, we suggested that this being a low residue food did not impair the characteristically diminished appetite of the adrenalectomized rat as did the high residue Purina. The fact that bread is a high carbohydrate food we emphasized as important in view of the well-known breakdown in carbohydrate metabolism in adrenal insufficiency.

Recent work of Zwemer and Truszkowski[2] and also Allers, Nilson and Kendall[3] appears to be of importance in the interpretation of our results. These workers have shown that a high potassium intake is detrimental to the life of adrenalectomized animals. In view of this finding, we have analyzed our diet and found the potassium content of the Purina to be 0·46 grams per cent, while that of the make of bread chiefly used was but 0·135 grams per cent. This result indicates that the low potassium content of the bread may have been a factor favouring survival in our rats so fed. Experiments are in progress to determine the relative importance of these factors.

Humidity and Insect Metabolism

ENTOMOLOGISTS have suggested that certain insects may show a greater rate of metabolism in dry air than in moist at the same temperature. They believe that such increased metabolism should cause a greater production of metabolic water, to compensate for evaporation from the insect's body, and maintain a constant ratio of water to dry matter at different atmospheric humidities. This increase in metabolic rate is assumed to occur in resting insects which are not moving actively. Buxton[1] obtained results which indicated that, at 23° C., the mealworm used up its reserves more rapidly in dry air than in moist, and kept the ratio of water to dry matter constant. As the body composition of mealworms is so variable, and as these results were obtained from rather small numbers, it appeared advisable to make further experiments before finally accepting a conclusion of such general physiological importance.

Numerous experiments were made, in which large numbers of individual mealworms were subjected to various humidities at temperatures ranging from 8° to 37° C.[3] Analyses after intervals of from 14 to 35 days showed that the rate at which the reserves were utilized was governed by temperature alone. For example, batches of these insects consumed reserves equal to 19 per cent of their dry weight in 35 days, when exposed to humidities of either 0 or 60 per cent at 24° C. I also made daily estimations of the amount of carbon dioxide produced by mealworms at different temperatures and humidities, and found that the rate of respiration appeared to be governed by temperature alone, and unaffected by changing humidity.

Experiments with other insects, including bed-bugs[4], clothes-moths[5] and adult[6] and pupal[2] tsetse flies all show that with them the rate of metabolism is governed by temperature, and unaffected by changes in humidity.

In the light of present knowledge, it is difficult to see how an increase in the rate of metabolism *could* help an insect to withstand desiccating conditions. True, it would produce more water of metabolism, but this would mean an increase in the rate of respiration (to obtain the extra oxygen) and consequently the spiracles would be opened more frequently. This would allow more water to be evaporated[7]. For every molecule of metabolic water produced, at least one molecule of oxygen must be taken in, and under dry conditions more water is lost by the evaporation which accompanies respiration than is gained by metabolism. This has been shown by analyzing insects which have been subjected to low humidities, and by the fact that many insects are more susceptible to desiccation at high temperatures (where metabolism *is* actually increased) than at low temperatures.

With an actively moving insect, an unfavourably low humidity may perhaps cause great activity, and a consequent increase in the metabolic rate; but this will hinder, rather than help in withstanding desiccation. With resting insects such as fasting mealworms, a lowering of the humidity does not increase the rate of metabolism; if the metabolic rate were increased, it would not be of any advantage.

Organizers in Mammalian Development

EMBRYONIC organizers, discovered in the Amphibia by Spemann[1], have since been found also in birds (Waddington[2]) and fish (Luther, Oppenheimer[3]). It seems probable that embryonic determination is brought about in the same way in all groups of vertebrates, and rather similar conditions have been found in some invertebrates. Previous work on mammalian embryos has, however, produced very little definite evidence in support of this suggestion. The occurrence of identical twins shows that regulation is possible in very early stages (see Nicholas[4]), while several authors have described apparently mosaic development of parts isolated from early somite, or later, stages.

The only available fact concerning the actual process of determination in mammalian embryos is that the ectoderm of the rabbit embryo in the primitive streak stage can be induced, by a chick organizer, to form neural tissue (Waddington[5], working with the tissue culture technique[6]). Attempts to obtain inductions by transplanting pieces of the rabbit primitive streak into other rabbit embryos have so far been unsuccessful, although the grafts differentiate into neural tissue and (probably somitic) mesoderm; small amounts of neural tissue have been found in grafts which did not include the anterior end of the primitive streak, the rabbit behaving in this respect exactly as does the chick.

Grafts may also be made from the rabbit into the chick, and the grafted tissues differentiate (Waddington and Waterman[6]). Until recently, no inductions were observed in these grafts, but this long-expected result has now occurred; in a specimen, No. 36—9ORC, the anterior part of the embryonic axis of a two somite rabbit has induced a small but definite neural plate in the host chick. This shows that the rabbit contains an organization centre, and, taken with the fact mentioned above that the rabbit ectoderm is competent to react to a chick organizer, scarcely leaves room for doubt that the determination of the mammalian embryo during normal development is in fact produced by an organization centre.

Metabolism of Cartilage

THE recent letter of Bywaters[1] on this subject prompts us to describe some observations made independently in the course of a study of normal mammalian tissues showing an anærobic type of metabolism. Following our investigation of the metabolism of the medulla of kidney[2], a tissue recognized as having a poor capillary supply, we were led to study cartilage because this is an entirely non-vascularized tissue, and here we found the same association of anærobic type of metabolism and poor oxygen supply as in medulla of kidney.

Our experiments were done with thinly sliced rib cartilage of the rat, suspended in a bicarbonate-saline medium. Concentration of glucose: 0·2 per cent.

Material	Respiration	Ærobic glycolysis	Anærobic glycolysis
	Q_{O_2}	$Q_G^{O_2}$	$Q_G^{N_2}$
Costal cartilage			
Specimen I	− 0·68	+ 1·22	+ 1·36
Specimen II	− 0 22	+ 1·27	+ 1·85
Xiphisternum	—	—	+ 0·90

These figures are much higher than those obtained by Bywaters for the rabbit; in particular, the respiration though small is easily measurable. Comparing the ratios of respiration, ærobic and anærobic glycolysis, we find roughly the same relationship for medulla of kidney, cartilage and tumours.

Approximate ratio	$Q_{O_2} : Q_G^{O_2} : Q_G^{N_2}$
Medulla of kidney	1 : 2 : 4
Cartilage	1 : 3 : 4
Tumours	1 : 2 : 4

Thus cartilage gives further support to the view previously expressed[2] that the metabolic type depends on the relationship between oxygen supply and energy requirements of the tissue.

Optical Polarization Ellipsoids of the Hydrogen Halide Gases

ESTIMATES of polarization and related constants of the four hydrogen halides[1] appear to reveal certain peculiar, though simple relations. If α is the mean optical polarizability of a halide HX, b_1, b_2 respectively that along and perpendicular to the internuclear axis of symmetry S, r_e the equilibrium internuclear distance of HX, and $\alpha(X)$ the polarisability of the negative ion X^-, I find that (1) $\alpha = 1{\cdot}242 r_e^3$ [2,3] and, further, if (2) $b_1 \propto r_e^3$, then since $3\alpha = b_1 + 2b_2$, (2a) $b_2 \propto r_e^3$, (2b) $b_1 \propto b_2$, and (2c) $b_1 = \alpha(X)$ (Born and Heisenberg[4]).

Stuart[5], arguing from the positive sign of the constant occurring in the electro-optical Kerr effect of hydrogen chloride, found that the direction of greatest polarisability b_1 coincided with the axis S, along which the permanent dipole also lies. If we take[1] $\alpha(\text{HCl}) = 2{\cdot}56$, and[5] $(b_1 - b_2)_{\text{HCl}} = 0{\cdot}77 \times 10^{-24}$ c.c., it follows that b_1, b_2 are $3{\cdot}07$ and $2{\cdot}30 \times 10^{-24}$ c.c. respectively. Using the above assumption (2), the corresponding values for the other halides may be calculated, as in the following scheme.

HX	b_1, b_2, $\frac{1}{3}(b_1+2b_2)$ (in c.c. $\times 10^{24}$)			α(HX) (expt.[1])	α(X) [4]	r_e
HF	0·96	0·72	0·82	0·80	0·99	0·864A.
HCl	3·07	2·30	2·56	2·56	3·05	1·272
HBr	4·19	3·14	3·49	3·49	4·17	1·411
HI	6·24	4·68	5·20	5·18	6·28	1·612

The anisotropy δ is connected with the depolarization factor Δ (ratio of light intensity scattered parallel and at right angles to direction of incident beam) for gas molecules having an axis of symmetry, as follows :

$$\delta^2 = \frac{5\ \Delta}{6 - 7\ \Delta} = \left(\frac{b_1 - b_2}{b_1 + 2b_2}\right)^2 = \frac{1}{9}\left(\frac{b_1 - b_2}{\alpha}\right)^2,$$

so that we have $\delta^2 = 0{\cdot}01007$, $\delta = 0{\cdot}1004$ and $\Delta = 0{\cdot}0119$ for each of the four cases. (Stuart[5] found $\Delta(\text{HCl}) = 0{\cdot}0125$, giving $b_1 = 3{\cdot}01$, $b_2 = 2{\cdot}24 \times 10^{-24}$ c.c.)

If we may take $\delta = 0{\cdot}1$, we have $10(b_1 - b_2) = b_1 + 2b_2$, whence $b_2/b_1 = 0{\cdot}75$, $b_1 = 1{\cdot}2\alpha = 1{\cdot}490 r_e^3$, $b_2 = 0{\cdot}9\alpha = 1{\cdot}117 r_e^3$, and $b_1 - b_2 = 0{\cdot}3\alpha$.

On the present basis of argument, therefore, I conclude that (1) the four hydrogen halides have equal optical anisotropies, (2) the optical polarization ellipsoids constitute similar solid figures, (3) b_2 is approximately equal to 75 per cent of b_1, and (4) b_1 of HX is equal to the polarizability of the halogen ion X^-, a somewhat surprising result. Dispersion of refractive index is neglected in making the estimates.

Further work on the depolarization and Kerr effects of the hydrogen halides other than hydrogen chloride is desirable to confirm these predictions.

Focal Depth of the Hawke's Bay Earthquake of February 2–3, 1931

IN the seismological report of the Hawke's Bay earthquake of February 2–3, 1931[1], an attempt was made to arrive at a value for the focal depth of the shock. The method used was similar to that developed by Jeffreys[2] for near earthquakes in western Europe, depending on the apparent delay of the surface wave *Pg*. In the Hawke's Bay earthquake, a phase agreeing reasonably well in velocity with *Pg* was observed on the seismograms at Arapuni, Takaka and Wellington, and the mean apparent delay led to a focal depth of 13 miles (21 km.). On account of the confused nature of the Wellington and Arapuni records, and the lack of precise time on most of the records, it was considered that a definite value for the depth could not be obtained, but that it probably lay between 10 miles and 15 miles (16–24 km.). In the original interpretation of the Takaka record, the first phase recorded after *Pn* was considered to be *P**, and the interval between *Pn* and *Pg* was 28 seconds.

In a recent paper[3], C. G. Dahm, of Saint Louis, U.S.A., had occasion to discuss the focal depth of the Hawke's Bay earthquake, using data from the Takaka seismogram. He found an interval of 7·5 sec. between what he considered to be the phases *Pn* and $\overline{P}$, and states that this agrees with a focal depth of 10 km. (6 miles). Dahm points out that the Takaka data are not conclusive, and after some further considerations, finally arrives at a focal depth of the order of 10–12 km. (6–8 miles).

Having rightly directed attention to the difference between his own value for the depth and that given in the Hawke's Bay earthquake report, Dahm criticises this report, considering that the methods used appear to be based on doubtful assumptions. In view of this criticism, I re-examined the original Takaka seismogram. On both horizontal components the first movement (presumably *Pn*) is very small and emergent, and the interval before the arrival of the second phase was found to be 8 sec. on the E–W component, and 11 sec. on the N–S component. This discrepancy of 3 sec. may be due to the arrival of *Pn* not having been recorded on the E–W component. On the vertical component, *Pn* is very small, but the interval to the next phase was observed to be about 10 sec. The mean interval between *Pn* and the next phase at Takaka therefore appears to have been of the order of 10 sec. No phase could be found to correspond with an interval of 7·5 sec., as read by Dahm, and if it is assumed that the second phase is *P*, then a focal depth somewhat greater than 10 km. is indicated. This would tend to diminish the discrepancy between Dahm's determination of the focal depth, and that given in the Hawke's Bay earthquake report.

It should be mentioned that the re-examination of the Takaka seismogram did not appear to warrant any serious alterations to the original interpretation from which the focal depth of 10–15 miles (16–24 km.) was determined. Further, although Jeffreys' theory regarding the waves in near earthquakes has been somewhat modified in a more recent paper[4], the apparent delay of the *Pg* wave would still lead to a determination of focal depth.

From the foregoing statements, it is considered that Dahm's interpretation of the Takaka seismogram is open to question, and that his criticism of the Hawke's Bay earthquake report is not justified.

Continuous Spectra of Certain Types of Stars and Nebulæ

MR. W. M. H. GREAVES[1] has made certain objections to my tentative explanation of secondary maxima in the continuous spectra of novæ, etc.[2], because the observations of Nova Herculis 1934 made by various observers do not fully agree.

I should like to point out that a close inspection of the curves given by Beileke and Hachenberg[3] discloses, however, the presence of a secondary maximum in most curves at practically the same wave-length as observed by Barbier, Chalonge and Vasy[4] and reproduced in my note. The results of the unpublished Greenwich observations are, of course, unknown here.

However, leaving aside the Nova Herculis 1934 spectrum, we find, in the spectra of several former novæ, the presence of secondary maxima upon which I based my theory of two different types of continuous emission spectra in novæ, etc., superimposed on each other. Whether or not one of these emissions is continuous electron radiation is an open question. I only wish to direct attention to this type of emission, the existence of which does not seem to be generally realized. This type of spectra is quite different from the Planck black body radiation on which most astrophysical theories are based. I believe that the continuous electron emission will help in explaining several phenomena observed which have not been accounted for so far.

The Teaching of Science in Schools

AN account of a conference on general science opened by the president of the Royal Society appeared in NATURE of April 11, p. 626. This association of prominent men of science with secondary education is very desirable. I write to suggest that the present is a very critical time for science teaching in schools, and that men of science may now be able to give help in a more effective way than by presiding at meetings and conferences.

Such help has been given in the past. In 1918 a committee of which Sir J. J. Thomson was chairman issued a report on the teaching of science and made many valuable suggestions. A few of these have been carried out, but only a few; in the meantime, conditions have altered, and the whole question needs reconsideration. The recent conference represents a belated attempt to implement recommendation No. 17 of that report:

"That the science work for pupils under 16 should include, besides physics and chemistry, some study of plant and animal life."

To do this in the limited time at the teacher's disposal presents difficulties, but this recommendation must necessarily be read in conjunction with recommendation No. 8:

"That in all secondary schools for boys the time given to science should not be less than 4 periods in the first year of the course from 12 to 16, and not less than 6 periods in the three ensuing years."

This was published nearly twenty years ago, when the great necessity was to obtain for science some sort of recognition in our educational system. It would be expected that what was recommended then would be axiomatic now. Surprising as it may appear, the very body which was partly responsible for this recent conference expressed the intention of trying to formulate a generalized course in chemistry, physics and biology to occupy only 4 periods a week; that is, 3 hours or a little less.

If this proposal comes into being, we shall be back again in pre-scientific times. If I read the recommendation of the Thomson committee aright, it did not maintain that the 6 periods a week was an adequate time, but merely that it was as much as many schools under present conditions could be expected to give. A considerable number of schools have now approximately that time. There is a danger that the publicity which has been given to a particular sub-committee may lead to reduction of this inadequate minimum of time which many science teachers already have.

The whole problem of the school time-table is now in hopeless confusion. No attempt is being made, for example, to correlate the mathematics and the science in the manner suggested by the Thomson committee. Teachers of mathematics and science scrupulously respect each others' territory. The dominant influence is that of a group of headmasters who wish to keep the classical bias of the time-table, and this is probably the origin of the proposal to formulate a scheme for 4 periods a week, a proposal which was originally suggested by the Secondary Schools Examination Council. The time is ripe for another committee, similar to the old Thomson committee, to reconsider the whole question in the light of the conditions of the present day.

Estimation of Vitamin A

WITH further reference to our letter under this title in NATURE of March 7, p. 402, we have been in touch with Dr. E. M. Nelson, chief of the Vitamin Division, United States Department of Agriculture, Food and Drug Administration, Washington, concerning the ambiguous position of the U.S. Pharmacopœia Reference Cod Liver Oil. Our query was, Are we sure that the "Reference Oil" now in use is identical with the original product ? In reply to our question he has given us permission to publish the following facts, which undoubtedly throw some light on a rather difficult situation :

"There has been only one lot of this reference oil prepared and the samples that have been issued were all bottled at the same time from this lot. Since the potency of 3000 units of vitamin A and 95 units of vitamin D were assigned to this oil, assays have been made at intervals by six laboratories for both its vitamin A and vitamin D content. There has been no indication that the oil has changed in vitamin potency. As soon as the oil was obtained samples were sent to Dr. Charles E. Bills of Mead Johnson and Co., for spectrophotometric determination of vitamin A. He has made several such examinations since that time. His last report was made to the U.S. Pharmacopœia Vitamin Committee on March 24, at which time he stated that as far as can be determined spectrophotometrically the oil has not changed in vitamin A potency."

Points from Foregoing Letters

THE atomic masses of doubly charged thorium 232, and of uranium 238, have been determined by Prof. A. J. Dempster with the mass-spectrograph, by comparison with the isotopes 116 and 119 of tin (having the same mass-charge ratio). The presence of 0·4 per cent of a stable uranium isotope of mass 235 was also found, and since a radioactive uranium isotope of mass 235 and of half-life 24 hours is already known, Prof. Dempster concludes that the two isotopes, having the same mass and charge, are isomers differing in nuclear properties.

Some previous observations of the conductivity, unimolecular racemization and halogen replacements of alkyl halides in sulphur dioxide and formic acid solution are interpreted by Dr. E. D. Hughes, Prof. C. K. Ingold and A. D. Scott as arising from the slow liberation of a negative halogen ion (Cl^-) followed by the rapid elimination of a positive hydrogen ion (H^+). The original saturated compound thus becomes unsaturated, as is shown by its subsequent ability to absorb bromine.

A possible chemical mechanism to explain how the addition of sodium sulphide or of certain primary amines helps the removal of hair from hides by fresh lime liquors is suggested by Dr. H. Phillips. These substances reduce the sulphenic acid side-chains to cysteine, and thus prevent the generation of aldehyde groups ; this facilitates the severing of the cystine disulphide cross-linkages of the keratin substance.

From the rate of sedimentation of solutions of thyroglobulin (the active constituent of the thyroid gland) under the influence of strong centrifugal forces, Dr. H. P. Lundgren concludes that it consists mainly of particles of 'molecular' weight 700,000. Low concentration of thyroglobulin or of salts, high temperature, high dielectric constant and *p*H above the isoelectric point have been found to favour the dissociation of thyroglobulin into components of lower particle weight.

The atomic heat of palladium between 2·5° and 22° K. has been determined by G. L. Pickard. He finds, in agreement with Mott's views, that it can be expressed as the sum of two factors, one due to lattice vibrations, which varies with the cube of the temperature, and another, the electronic specific heat, varying directly with the temperature and due to unfilled quantum states (positive holes).

The transparency of thin films of sodium and potassium in the far ultra-violet (Schumann region) has been determined by Prof. W. H. Watson and D. G. Hurst. They point out the value of sodium films as filters to remove the visible and ultra-violet light above 2100 A., and direct attention to the conflict between experimental results and the existing theory of the optical properties of metals.

Rats from which the adrenal body has been removed live longer if fed on bread than when fed on Purina Dog Chow. Dr. R. A. Cleghorn and G. A. McVicar suggest that this is due to the lower potassium content of the bread, since it has been shown that potassium is detrimental to adrenalectomized animals.

By grafting on to chick embryo the anterior part of the embryonic axis of a two somite rabbit, a small but definite neural plate was induced in the host. This, C. H. Waddington states, shows that the rabbit contains an organization centre, and is additional proof that determination of the mammalian embryo is in fact produced by an organization centre.

Dr. C. H. Douglas Clark finds that the optical polarization ellipsoids of the four hydrogen halide gases constitute similar figures having equal anisotropies and depolarization factors. He calculates the polarizabilities for the four cases, and finds that the polarizability at right angles to the internuclear line is about 75 per cent of that along this line, and is equal to the polarizability of the corresponding negative ion.

In view of the divergence in the interpretation of the seismograms of the Hawke's Bay earthquake of 1931 and the calculations of the focal depth therefrom, R. C. Hayes has re-examined the original Takaka seismogram. Its record, he states, confirms in the main the original interpretation, from which a focal depth of 16–24 km. was inferred.

Referring to the note in this column (July 11, p. 81) on "Inactivation of Crystalline Pepsin", Dr. J. Steinhardt states that the fifth-power relation reported in his communication does not extend over the small interval *p*H 6·2–6·45, but from the most acid solutions measured to *p*H 6·45. The velocity interval was over 1 to 5,000, while the smaller interval given in the synopsis is equivalent only to a range of about 1 to 15.

Research Items

Actions of Acetylcholine on the Brain

THE pharmacological actions of acetylcholine are of particular interest because, in almost every case in which this substance has been shown to have an action in the body, evidence has been obtained of the presence of a nerve which liberates acetylcholine locally in such a way as to produce this action. Henderson and Wilson have recently filled an important gap in our knowledge of the actions of this substance (*Quart. J. Exp. Physiol.*, 26, 83 ; 1936). They have injected acetylcholine into the ventricles of the brain in man. This causes vomiting, intestinal peristalsis and sweating. Its effects on the heart rate, blood pressure, respiration, the pupil, etc., were small and inconstant. The injection of eserine caused similar effects, and potentiated the effect of a later injection of acetylcholine. These effects were produced by comparatively small doses, and it is clear that they were due to a local action on the brain and not to a general action after absorption into the general circulation. Atropine, injected into the ventricles, prevented or abolished the effect. Apart from the interest of the observations themselves, these results are important because they suggest that certain impulses may be transmitted chemically by acetylcholine across synapses in the central nervous system.

Flour Beetles of the Genus *Tribolium*

THE small beetles of this genus are of great economic importance since they are able to subsist on a wide variety of food materials, and have become widely distributed through commerce. The ease with which they can be reared under controlled environmental conditions has also marked them out as very suitable material for population studies and other kinds of laboratory investigation. In Technical Bulletin No. 498 (March 1936) of the United States Department of Agriculture, Mr. Newell E. Good has brought together a mass of useful information respecting the biology, habits and control of the species of *Tribolium*, together with a selected bibliography of the genus. Keys are given as an aid to the identification of the economically important species, which are also admirably figured. Although primarily written from the economic point of view, the Bulletin will prove useful to laboratory workers also. In the latter connexion, the tabular data respecting development at specified temperatures and on oviposition and longevity may be specially mentioned.

Spotted Wilt Virus and the Hormone Heteroauxin

WE have received a communication from Dr. B. J. Grieve, of the Department of Botany, University of Melbourne, in which he describes the results of his investigations into the action of the spotted wilt virus upon the growth regulator heteroauxin. It is well known that spotted wilt arrests the growth of infected tomatoes, and it seemed likely that the virus inactivated the growth hormones in these plants. The technique of Went was first used to compare the effects of diseased and healthy juice upon the inward curvature induced by heteroauxin on split pea stems. In four experiments, such curvatures were observed upon the stems placed in healthy juice with heteroauxin, but were absent from those treated with virus juice and the hormone. This seemed to show an inactivation of the growth regulator by the virus, but a further number of similar experiments did not indicate any difference between the two kinds of treatment. Another and more conclusive method of study involved the injection of various amounts of heteroauxin into healthy, and into diseased, tomato plants. Adventitious roots appeared upon the stem in the majority of healthy plants, but did not form upon diseased tomatoes, unless the plant appeared to have thrown off the disease. The inhibitory action of spotted wilt virus on heteroauxin is not shared by two other viruses which were used, namely, tobacco viruses 1 and 6.

X-Chromosome of *Drosophila*

THE *X*-chromosome of *Drosophila melanogaster* and *D. simulans* contains near the end an enlargement or 'bulb' in the salivary gland chromosome, the nature of which has been investigated by Dr. C. A. Offermann (*J. Genetics*, 32, 103). He finds that the bands run obliquely in two series in the 'bulb', and that it represents a symmetrical duplication or 'branch' of a short chromosome segment. This might arise through three breaks and two re-attachments in a pair of chromosomes, or by five breaks and three re-attachments. In either case, one of the breaks must occur at the same level in both chromatid strands. As the 'bulb' occurs in two closely related species, it must have arisen in their common ancestor and must therefore be a stable feature of the chromosome. This is accounted for by the fact that crossing-over can occur between the two arms of the duplication, the bands of which are in reverse order. The less condensed appearance of the 'bulb' in salivary chromosomes of the male than in the female is attributed to a lesser synaptic attraction between the chromonemata in the male nuclei.

Strength Tests of Structural Timbers

UNDER this title in *Forest Products Research Records*, No. 8, Part I dealt with general principles, with data on redwood from Gefle and Archangel. Part 2 of the same series (April 1936) deals with general procedure of selecting and testing joists, with data on British Columbian Douglas fir (*Pseudotsuga Douglasii*) by C. J. Chaplin and E. H. Nevard. The tests were carried out with small clear specimens and also on a full scale : the results are of considerable interest. In summarizing them, the Director of the Princes Risborough Laboratory says that "A comparison between the results given in this report and those published by the Forest Products Laboratories of Canada may show an apparent discrepancy in the strength values. This is due to difference in the relation between width and depth of cross-section of the pieces tested and to differences in character which may occur between samples of the timber. Such differences in character must be expected where a wide range of the timber is dealt with in the country of origin. The Forest Products Research Laboratory at Princes Risborough accepts completely the validity of the Canadian figures, and urges their use in all circumstances concerning the strength of Canadian Douglas fir. The same applies to results published by the Forest Products Laboratory at Madison, U.S.A., for Douglas fir grown in that country."

Experiments with 'Electrets'

A COMMUNICATION entitled "The Disengagement of Energy in Melting Electrets" has been received from Drs. G. Groetzinger and H. Frei, of the University of Vienna. An 'electret' is produced by solidifying certain types of wax, for example, carnauba wax, in a strong electric field. The wax thereby acquires a polarization, in the direction of this applied field, which may be retained unimpaired over very long periods of time. It may be said to be the electrical equivalent of the permanent magnet. A paper by A. Gemant, published in the *Phil. Mag.* (20, 929; 1935) describes much research work on the subject, with a bibliography of earlier papers. Drs. Groetzinger and Frei state that, when an electret is melted, the stored charge is released as an electric current, and that this charge is the same whether the electret is melted immediately or several days after its preparation. This, however, is to be expected, since it is known that electrets can retain their original charge for a considerable period. The authors also record that, when the electric field is applied to an already solid sample of the electret material, the stored charge is much less than before, and instead of being retained, as in the normally produced electret, it disappears fairly rapidly. This is quite a normal procedure, and the experimental result is what would naturally be expected.

Transmutation of Platinum by Deuterons

TRANSMUTATION by bombardment with artificially accelerated deuterons, which is nearly general among the light elements, has now been observed with very heavy elements. J. M. Cork and E. O. Lawrence (*Phys. Rev.*, 49, 788, June 1) have bombarded platinum foils with deuterons of maximum energy 5×10^6 volts. The induced radioactivity was composite in character; periods of 28 min., 8·5 hr., 49 min., 14·5 hr. were detected, and a chemical investigation showed that the first two periods were associated with iridium and the second two with platinum. Both positrons and electrons were emitted. The transmutation of such heavy elements is not to be explained on the Gurney-Condon-Gamow theory of the penetration of potential barriers, and the formation of iridium isotopes is not explained by the theory of Oppenheimer and Phillips, in which only the neutron part of the deuteron enters the nucleus. The direct action of secondary neutrons was excluded by a special experiment. The production of iridium isotopes probably follows the entry of deuterons of special velocities into the nucleus by a 'resonance' process, and the dependence of transmutation efficiency on deuteron velocity is in accordance with this view.

Velocity of Rapid Reactions

SOME years ago, Hartridge and Roughton devised a method for the study of rapid reactions in which two solutions were mixed and then made to flow down a tube. The progress of the reaction at points along this tube was measured by optical methods. The method has now been improved by the use of photo-electric cells and by reducing the scale of the apparatus (F. J. W. Roughton and G. A. Millikan, *Proc. Roy. Soc.*, A, 155, 885, June 2). The mixing arrangements and the character of the flow down the tube have been specially studied. The smallest apparatus may be used with 20–30 c.c. of fluid to study reactions with half-periods of 0·0005 sec. Some experiments on reactions which have been studied by other methods confirm the validity of the method.

Low Temperature Carbonization of Coal

THE Department of Scientific and Industrial Research has published the results of tests made in accordance with a standing arrangement by the Director of Fuel Research on a plant erected by the Coal Research Syndicate, Ltd., at Mansfield, for the carbonization of coal at low temperatures (London: H.M. Stationery Office. 9*d*. net). The process has interesting features. A charge of lump coal (35 tons), almost devoid of caking properties, is carbonized in a chamber 10 ft. in diameter and 25 ft. high by the combustion at the top of the column of part of the gas made. The products of combustion and distillation are drawn downwards through the charge, and leave the bottom for the gas treatment plant. A portion of the gas is returned to the top of the carbonization chamber when, as mentioned above, it is burnt after the addition of air. At the end of the carbonization, the bottom of the retort is withdrawn by hydraulic gear, and the whole charge is dropped for quenching. The coke product was found, on test, to be a satisfactory fuel for the open grate. This process is interesting because, unlike most low temperature processes, it handles the material in bulk comparable and exceeding that in modern coke ovens.

Development of the Coiled-Coil Lamp

IN the *Technical Review* of April published by the Philips Laboratory, Eindhoven, Holland, there is an instructive paper by W. Geiss on the development of the coiled-coil lamp. The first material used for lamp filaments was carbon and later graphite. A further increase in temperature was made possible by the adoption of metals with high fusion points like osmium, tantalum and tungsten. At present, tungsten is considered the best material for lamp filaments. To obtain a high efficiency, it is essential to keep the rate of volatilization as low as possible. A 'filling' of argon or nitrogen at 50–100 cm. pressure greatly diminishes the rate of volatilization. Unfortunately, the gas filling increases the losses by thermal conduction and convection. In this respect thick filaments give much more satisfactory results than thin ones. If a long thin filament is wound in the form of a spiral, its total heat losses are of the same order as for a filament of the same length and cross-section as the spiral. It has been found possible to reduce the effective length of the coil still farther by winding the coil itself round a core, and this gives the 'coiled-coil' arrangement. The first attempts to use coiled coils were made twenty years ago, and failed mainly because the filaments expanded during service. By suitable pre-treatment, this difficulty was overcome. A mixture of argon and nitrogen has been used for filling these lamps. If krypton or xenon were used as a filling, the heat losses would be greatly diminished. Whether they will ever be used depends on the progress that is made in isolating these rare gases. If the flux from a single-coiled and a coiled-coil lamp is the same, the saving in power in the latter lamp is 7–10 watts; in addition, it maintains its efficiency better during life. The increase in the efficiency obtained by coiling the filaments is more marked for lamps of small candle-power.

Tercentenary of the University of Utrecht

ON June 22–24, a brilliant sun shone on the ancient and famous city of Utrecht, thronged with students and visitors from many lands and gaily decorated with the national flag of Holland and the colours of all the Faculties. The occasion was the celebration of three hundred years of the University's existence. To Utrecht had come the representatives of most of the universities and learned academies of the world, to pay homage and do honour to her ancient and distinguished university. Amidst the scarlet gowns and many coloured hoods of the professors and academicians flashed the white plumes of the horses and the gay cockades of the splendid coachmen of the students' carriages, for to Utrecht had also come the representatives of the students' "senates" from all the universities of Holland, and the associations and clubs of old University of Utrecht men from every part of the country. In this land won by brave men from the sea, where freedom dwells and learning flourishes, all had met to place another milestone on the long road of civilization, wherewith to mark the completion of the third century of a great university's beneficent life.

During the forenoon of Monday, June 22, the associations and clubs of former members of the University came with their banners in a procession from the station, whilst a great carillon pealed and thundered from the thirteenth century tower of the Cathedral Church. In the afternoon, gifts were presented to the University. At eight o'clock in the evening, the foreign delegates, representing universities and learned academies and societies, were received by the Council and Senate in the great Hall of the University, while at nine o'clock the municipality of Utrecht held a reception in the rooms and beautiful garden of the Municipal Art Gallery.

Serious business began on Tuesday, June 23. In the morning the delegates, in academic robes and decorations, were received by the University in the Church of St. Peter. Addresses of welcome were delivered by Dr. S. Jacob, the President of the Council, and Prof. C. H. Vollgraff, the Rector Magnificus. Speeches of congratulation and thanks were then made by Prof. J. Huizinga, of the University of Leyden, and by several foreign delegates, including Dr. Clarke, of the University of Oxford. The University hymn, "In Babylonia", was played on the viola, with organ accompaniment, by Mrs. Vogelsang. As the name of each delegate was called, he came forward and presented an address of congratulation to the President and the Rector. Then the members of Council, the professors of the University of Utrecht and the foreign delegates walked in procession from the Church of St. Peter to the Cathedral Church, where lunch was provided in the cloisters and the beautiful old cloister garden. Among the other English delegates present may be mentioned Prof. G. Barger (representing the University of Edinburgh), Prof. F. G. Donnan (representing the Royal Society and the University of London), and Prof. D'Arcy Thompson (representing the Royal Society of Edinburgh and the University of St. Andrews).

After lunch, the great procession of professors and delegates walked through the streets of Utrecht, which were thronged by enormous crowds of citizens and guarded by cordons of police. This brilliant and most impressive scene was watched by the Queen of Holland and the Princess Juliana. The procession returned by a different route to the Cathedral Church, where a solemn service of commemoration was held in the presence of the Queen and the Princess, and a great gathering of invited guests, including many high officers of the army and navy and high officials of the State. After some of the beautiful organ music of Bach, addresses were delivered by the President of the Council and the Rector Magnificus, the latter giving a long account of the struggle of Western civilization for freedom of learning and liberal government. Then came a very interesting ceremony, the presentation of the first gold medal of honour of the University to the Queen, to which Her Majesty made a suitable reply of thanks. After some more organ music, a short and eloquent address was delivered by His Excellency the Minister of Education, Art and Science. The proceedings were concluded by the ceremony of attaching the third centenary ring to the pole of the great banner of the University.

After the commemoration service, a number of foreign delegates were presented to the Queen, and as the great procession again filed out of the Cathedral Church, a carillon was played by J. A. H. Wagenaar.

In the evening, a banquet was given by the Senate of the University, at which many delegates made speeches of congratulation and thanks. After the banquet the guests were taken by bus to a wonderful open-air performance by members of the Students' Associations. This was a dramatic pageant entitled "De Groote Geus" (The Great Vagabond). The façade of a great castle had been erected in a large meadow, representing the stronghold of a Spanish noble. In front of this the peasants and citizens held a market fair. Then came the "Groote Geus"—the Dutch Tilleulenspiegel—with his jesters and his jests, to amuse the people and by sarcastic innuendo to arouse them from their bondage. Their anger grew, but Spanish horsemen and men-at-arms poured from the castle gates to quell them. Finally, the Hidalgo with his chatelaine and retinue came out to witness a masque prepared by Tilleulenspiegel. But the people saw what he meant—it was a masquerade of the "Fat- and swollen-headed overlords". In a burst of rage and anger, they stormed and burnt the castle. The drama thus represented the struggle of the Netherlands for freedom from the Spanish yoke. It was a fine performance, played by something like three hundred students, with elegant costumes and elaborate flood-lighting effects. High praise must be accorded, not only to the author, producer and director, but also to the excellent acting and speaking of Tilleulenspiegel, who had a very heavy part. A special and very enjoyable feature of the pageant was the dramatic music, which was played from behind the façade by the municipal orchestra. This music was specially composed for the occasion by Dr. H. E. Enthoven.

The forenoon of Wednesday, June 24, was taken up by the conferring of honorary degrees on a number of delegates in the Great Hall of the University. Among those who were thus honoured may be mentioned Sir Henry Dale, Prof. Herbert Freundlich (University College, London), and Dr. Clarke (University of Oxford). At midday the delegates and their ladies were entertained to lunch in the cloisters and cloister garden of the Cathedral Church, after which they witnessed the march past the University of the students' "Masquerade". This was a dramatic procession of pikemen, mounted knights, etc., of which the special feature was the "Prince of Orange" and his retinue.

In the afternoon, there was a very enjoyable excursion (by autobus) into the province of Utrecht, including a visit to Hilversum and its new town hall (a fine building in the modern unadorned style) and tea in the park of the Chateau Deynselburg, given by Madame and Dr. S. Jacob. On returning to Utrecht, the guests paid homage to the "Prince of Orange", who held a Court.

The day concluded with a gala concert in the Tivoli Concert Hall, conducted by the famous Willem Mengelberg. The programme was: *Sol Justitiae*: a hymn dedicated to the University of Utrecht on the occasion of the third centenary (composed by Dr. H. E. Enthoven); *Piet Hein*: a Dutch rhapsody (composed by Dr. P. G. van Anrooy); Overture to the "Taming of the Shrew" (composed by Dr. Joh. Wagenaar); Beethoven's Fifth Symphony.

The music was well played by the municipal orchestra under the spirited leadership of Mengelberg. An amusing incident was the arrival of the "Prince of Orange" and his retinue. Even the great Mengelberg had to come down from his rostrum and pay homage!

Thus ended three wonderful days of lavish Dutch hospitality, academic ceremony and students' pageantry. As if in remembrance of the University motto, *Sol Justitiae, illustra nos*, the sun shone brightly on the gay scene of scarlet gowns, white-plumed horses, knights on horseback and the great Prince of Orange. The professors of the University amply sustained the honour of their city and their country in offering very kind private hospitality to many of the invited guests.

It was a great demonstration of the universality of learning, of the brotherhood of truth and freedom. As one stood in the peaceful cloister garden and listened to the carillons from the ancient tower, the message of a noble civilization resounded in one's ears. One was glad to feel that Holland had kept the sweet music of her old carillons and in the benign tolerance of a greater humanity had won the freedom of her soul.

F. G. DONNAN.

Fractures in Metals and Brittle Materials

A DISCUSSION on "Fractures in Metals and Brittle Materials" was held at the Royal Society on Thursday, June 11. Many points of importance were brought out in this interesting discussion, and it is perhaps difficult in the small space of a general article to do justice to them.

In introducing the subject, Dr. H. J. Gough presented a review of the present position of knowledge in regard to the understanding of the mechanism of failure. As regards metals, he holds that in view of their essentially crystalline structure the required physical explanation must be in terms of atomic structure before any real progress in ideas can be achieved. Stripped of non-essentials, the problem is that of obtaining an understanding of plastic deformation and a realization of the exact conditions under which a crack is formed. He emphasized the disability of not having available a satisfactory conception of the laws of cohesion in the metallic state, and the extreme value of any new contribution in this direction. Elasticity is an expected property in a metallic crystalline aggregate, but plasticity is a property which is extremely difficult, at the present time, to understand.

The study of single crystals is very helpful since the processes of deformation and fracture are characteristics associated with the crystal structure, and effects in crystal aggregates are modifications of the effects occurring in single crystals. The geometrical aspects of deformation are established, but give no information on the mechanism of fracture. While stressing the fact that the characteristics of deformation and fracture are probably capable of explanation in terms of single crystals, it must be remembered that the strength of polycrystalline aggregates depends to some extent on crystal size, so that an understanding of the part played by the crystal boundaries is a very important factor in the solution of the whole problem. No established explanation has yet been provided in regard to work-hardening, strain hysteresis, twinning and the process of conversion of strain energy indefinitely into heat energy.

Assuming that the mechanism of fracture is essentially a property of the individual crystals, Gough and Wood have described, in a recent paper, an investigation by X-ray methods into the physical system prevailing after different numbers of cycles in fatigue tests. It would appear that at fracture the physical system is the same under all conditions. Under a safe range of stress the damage to the crystal structure is not progressive, but a stable state is reached, whereas under an unsafe range of stress progressive change takes place. The changes in the neighbourhood of the ultimate fatigue crack are characteristic and exactly similar under all unsafe ranges of stress, and in this area the original structure is destroyed and new crystallites formed. This appears to be a definite advance in knowledge.

Prof. G. I. Taylor confined his remarks chiefly to the more precise mathematical theory of internal flaws. If one crystal is deformed, and hardening is produced in the crystal, additional stresses are imposed on the surrounding crystals, which therefore tend to become deformed. In steel at the yield point the stress is reduced on deformation. In this case the deformation tends to proceed in the same crystal and an irregular deformation results.

If the material has internal flaws—such as might be represented by small spherical and ellipsoidal cavities—the stresses acting locally are increased. Failure under these local stresses would be expected to occur when certain critical combinations of shear and direct stress are reached. (The exact relationships between shear and direct stress which follows from Mohr's hypothesis and from that of von Mises differ somewhat.) A special case is that where the cavity is filled with a material. For simple shapes of cavity, the stresses can be calculated, and one result is that if a flaw is assumed to be ellipsoidal, then the greatest concentration of stress may occur with the direction of the flaw at 45° or at right angles to the direction of principal stresses, according to the relative compressibility of the 'inclusion'.

Prof. L. N. G. Filon dealt chiefly with the different types of fracture which occur in solids, and illustrated his remarks with a large number of fractures in cast iron and glass. In ductile materials, slip does not always occur at 45° to the principal stresses. A fracture in a strip of mild steel broken in tension showed a fracture at approximately 60° to the line of the principal stresses. This was not due to any assymetrical properties of the steel, since a second slip line clearly shown by the material was exactly symmetrical with the first. In cast iron, brittle fractures can be obtained by a bending operation in which pure tension is applied to some parts of the material, and pure longitudinal compression in other parts. In this case fracture occurs at right angles to the stress lines. A curious 'staircase' fracture has been observed in these brittle materials in which the fracture began at right angles to the tension, but after passing through the material for some distance, branched along the line of tension, and branched back into the original direction and gave a step. In some cases several steps were observed. The conclusion reached was that in the same material the type of fracture obtained depends on the method of application of stress.

The possible effects of sub-microscopic cracks was the chief point discussed by Prof. E. N. da C. Andrade. He considers that the existence of surface cracks has been well established in three series of experiments. A strip of mica loaded so that the edges are stress free has a strength of about ten times the normal value. Andrade and Martindale in experiments on thin metal films on glass, diamond or other substance, have found that recrystallization proceeds on definite lines on the surface. These lines do not appear when the film is produced on the very perfect cleavage faces of mica. Indirect evidence of these surface cracks is afforded by experiments of Roscoe on cadmium wire, which had its critical shear stress increased to double the normal value when coated with a thin film of oxide a few molecules thick. It is well known that freshly drawn threads of quartz and glass are stronger than old threads. Griffiths believes this to be due to the absence of cracks in the freshly formed threads. In concluding, Prof. Andrade indicated briefly some of the difficulties of forming a theory of plastic deformation. In plastic materials, twinning and gliding take place on the twinned material in a way which is very complicated even in single crystals.

Dr. W. H. Hatfield said that the stress which may be safely applied is far removed from the stress which produces fracture, and that from the point of view of the engineer and metallurgist, the actual mechanism of fracture is less important than a satisfactory explanation of the means which are effective in increasing the safe range of stress. In iron, the fatigue range of the crystalline aggregate is increased and the stress to produce initial plastic deformation is also increased by 'sprinkling' particles of a hard, brittle substance, carbide of iron, through the mass of the ductile metal. It requires to be explained how the presence of such carbide particles raises the stress required to produce initial deformation in the continuous matrix of ductile ferrite. An increase in the value for the stress up to which strain is proportional to stress is difficult to understand. Particles of other hard brittle materials such as slags, sulphides, etc., do not have the same effect, in that they leave the yield point and maximum stress unaltered, but the ductility is very much decreased. It seems, therefore, that the adhesion and cohesion between the ductile matter and the particular inclusions is an important factor. An interesting fact which requires explanation is the influence of cold work on the fatigue values. It seems peculiar that a process of plastic deformation should increase the resistance to fracture. Much has been written on the effect of grain size, but it is easy to overlook the fact that to modify grain size as the only variable is extremely difficult, if not impossible. The causes of the modification of grain size may well be the real cause of the apparent effect of grain size.

Prof. P. B. Haigh's contribution was of particular interest in that it could be considered that his observations postulated a resuscitation of the idea of stress in metals translating the crystalline to the amorphous phase. When a slip band is formed in a crystalline ductile metal, the increase in the volume from the crystalline to the amorphous state tends to produce fluid pressure in a core surrounded by increased shear stress, and the band tends to spread across planes of easy cleavage in the grain.

Mr. S. A. Main suggested that more work on the speed of testing and the influence of temperature might lead to further information on the main problem. He also referred to the characteristic appearance of slip bands which are visible under the microscope and are therefore of a different size from Gough's 'crystallites'. There can be little doubt that the characteristic separation of the bands has a fundamental bearing on the problem.

Sir Robert Hadfield, in a written contribution, said that when attending trials of projectiles against modern armour, he had often observed that there seemed to be little difference in the appearance of a fracture, as compared with the fractures met with under ordinary static or dynamic conditions at comparatively low velocities of impact. Nevertheless, there were instances of remarkable differences in behaviour of various steels according to the manner in which they were tested, that is, whether comparatively slowly or rapidly. Some materials like over-heated mild steel, tough under slow stressing, are quite brittle at moderate speeds of testing. Mild steel of ordinary good quality is tough at all normal speeds used in impact testing, but tends to break with a brittle fracture when attacked at high speeds with rifle bullets. With regard to the effect of low temperature, there seems to be no simple explanation of the different responses made by different metals. Thus the retention by nickel of its toughness at very low temperature is not simply explained by its particular type of cubic structure, namely, the face centred cubic, in contrast with that of iron, which is body centred cubic.

The discussion was an extremely valuable one, and has served to indicate many directions in which intensive investigation can usefully proceed.

Research Fellowships and Grants

ROYAL SOCIETY AWARDS

THE Council of the Royal Society decided in the spring of this year to found an E. Alan Johnston and Lawrence research fellowship in medicine by means of funds available to the Society by bequests under these two names. The value of the stipend is £700 per annum, plus superannuation allowance. Seventeen candidates applied for the fellowship and of these, four were selected for special consideration. Council would gladly have appointed any one of them to a fellowship had four fellowships been available. The reception of the fellowship is a strong indication that candidates of high merit are available for full-time research posts in medicine. Council finally selected Dr. John McMichael, of Edinburgh, to work at the Edinburgh Royal Infirmary on the pathology of heart failure. From 1934 to 1936 he has been a lecturer in human physiology at Edinburgh. He has been offered special facilities for his work at the Edinburgh Royal Infirmary.

The Council of the Royal Society has also approved plans for medical research on malaria and on nutrition in India, involving a total expenditure of more than £8,000 in the next five years. Colonel Sinton has been appointed to investigate certain aspects of malaria at the Horton Centre. Another series of investigations on malaria, in conjunction with the London School of Hygiene and Tropical Medicine, provides for a study of mosquitos in the tropics, and Dr. C. Wilson has been offered a research appointment to enable a survey of nutritional conditions in India to be undertaken.

LEVERHULME FELLOWSHIPS AND GRANTS

Awards of Leverhulme fellowships and grants in aid for research for 1936 have been made to the following, among others, the subject of research being indicated in brackets: Dr. Agnes Arber (studies in the principles of angiospermous morphology and in the history of botany); S. J. Duly, head of the Department for the Scientific Study of Commercial Products, City of London College (carriage of goods by sea); Dr. F. Fairbrother, senior lecturer in chemistry, University of Manchester (the study of electrolytic dissociation processes and the mechanisms of chemical reactions by the use of induced radioactivity); C. P. Fitzgerald (sociology of the non-Chinese tribes of Yunnan, S.W. China); S. D. Garrett, formerly assistant plant pathologist, Waite Agricultural Research Institute, University of Adelaide, South Australia (biological antagonism of the soil microflora towards root disease fungi or crop plants—renewal of present fellowship); Dr. J. de Graaff Hunter, lately director of the Survey of India (planning and execution of geodetic triangulation of great extent); Mrs. K. Lonsdale, research worker, Royal Institution (relation between structure and physical properties of organic molecules—renewal of present fellowship); E. P. Mumford, lately director of the Pacific Entomological Survey, Honolulu (terrestrial and freshwater biota of the Marquesas Islands—renewal of present fellowship); F. R. Perry, member of Research Department, Metropolitan-Vickers Electrical Co., Ltd., Manchester (the study of overvoltages due to lightning on transmission lines—renewal of present fellowship); Dr. A. L. Reimann, research physicist, General Electric Company, Limited, Wembley, Middlesex (electronic conduction phenomena in solid insulators and semi-conductors); Dr. R. H. Thouless, head of the Department of Psychology, University of Glasgow (research in visual perception); Dr. W. E. Williams, lecturer in physics, King's College, London (determination of the vacuum wave-lengths and the structures of spectral lines by means of his reflection échelon).

Grants in aid of research have been made to the following: Prof. A. E. Boycott, late Graham professor of pathology, University of London (ecology and genetics of British non-marine Mollusca); Prof. H. J. Fleure, professor of geography, University of Manchester (physical (racial) characteristics of the peoples of Wales); Prof. J. W. Heslop Harrison, professor of botany, Armstrong College, Newcastle-on-Tyne (researches on evolution and heredity—renewal of present grant); T. N. Hoblyn, statistician, East Malling Research Station, Kent (technical problems in the layout and conduct of horticultural field experiments under tropical and sub-tropical conditions); Dr. W. H. Pearsall, reader in botany, University of Leeds (growth of Algæ); Dr. O. W. Richards, lecturer in entomology, Imperial College of Science and Technology, London (habits of South American bees and wasps); Prof. C. W. Valentine, professor of education, University of Birmingham (psychology of early childhood). A Leverhulme travelling fellowship has been awarded to Mr. A. Ruscoe Clarke on the nomination of the Medical Research Council.

Particulars of these awards can be obtained from the Secretary, Leverhulme Research Fellowships, Union House, St. Martins-le-Grand, London, E.C.1.

BEIT MEMORIAL FELLOWSHIPS

The trustees of the Beit Memorial fellowships for medical research have made the following awards, the subject and place of research being given after the name of each new fellow: *Fourth Year Fellowships* (£500 a year): Dr. E. S. Horning, to continue his research on the cancer-producing effects of œstrogenic compounds, and on the possibility of producing tumours *in vitro* (Imperial Cancer Research Fund, Queen Square, London); Dr. W. J. Dann, to continue his work on the vitamin B_2 complex in reference to the treatment of pellagra (Duke University School of Medicine, North Carolina, U.S.A.). *Junior Fellowships* (£400 a year): Dr. I. Berenblum, to study the mechanism of skin irritation by chemical substances in reference to their action as exciting or preventing the development of cancer (Dunn School of Pathology, University of Oxford); D. D. Woods, to study the metabolism of the anaerobic bacteria, and the phenomenon of adaptation in bacteria (Dunn Institute of Biochemistry, University of Cambridge); Dr. A. Neuberger, to study the carbohydrate group in proteins and its possible relationship to their antigenic properties in bacterial immunity (Department of Pathological Chemistry, University College Hospital Medical School, London); C. W. Bellerby, to investigate the control of the reproductive cycle by the anterior lobe of the pituitary (Department of Social Biology, University of London); Dr. T. W. Birch, to attempt to identify the component parts of the vitamin B_2 complex (Nutritional Laboratory, Cambridge); Lilian M. Pickford, to study the part played by the posterior pituitary gland in the control of water excretion by the kidneys (Pharmacological Laboratory, University of Cambridge); Dr. R. J. Pumphrey, to investigate the sensory physiology of insects, and the electrical response in the central nervous system to peripheral stimulation of afferent nerves (Zoological Laboratory, University of Cambridge); T. A. H. Munro, to study the role of inheritance in mental disorder (Research Department, Royal Eastern Counties Institution, Colchester).

AWARDS OF ROYAL COMMISSION FOR THE EXHIBITION OF 1851

The Science Scholarships Committee of the Royal Commission for the Exhibition of 1851 announces the following appointments for 1936: *Senior Studentships:* Dr. R. C. L. Bosworth, for research in chemical physics at Cambridge; N. A. Burges, for research in mycology at Cambridge and the Strangeways Research Laboratory, Cambridge; T. T. Paterson, for research in geology and prehistory at Cambridge; A. F. Rawdon-Smith, for research in physiology and psychology at Cambridge; Dr. D. Shoenberg, for research in physics at Cambridge. All the above awards were made on the recommendation of the University of Cambridge. *Overseas Scholarships:* D. G. Hurst, for research in physics at the Universities of California and Cambridge; J. Marsden, for research in physical chemistry at the University of Cambridge; on the recommendation of McGill University, Montreal. A. D. Misener, for research in physics at the University of Oxford or Cambridge; S. L. Cohen, for research in biochemistry at the Technische Hochschule, Zurich; on the recommendation of the University of Toronto. H. C. Corben, for research in theoretical physics at the University of Cambridge; on the recommendation of the University of Melbourne. R. N. Robertson, for research in botany at the University of Cambridge; on the recommendation of the University of Sydney. I. E. Coop, for research in physical chemistry at the University of Oxford; on the recommendation of the University of New Zealand. Dr. B. G. Shapiro, for research in biochemistry at King's College Hospital, London; on the recommendation of the University of Cape Town. C. O'Kelly, for research in experimental physics at the University of Cambridge; on the recommendation of the National University of Ireland.

SALTERS' INSTITUTE AWARDS

The following awards for 1936–37 have been made by the Salters' Institute of Industrial Chemistry and approved by the Court of the Salters' Company: Fellowships renewed to: E. I. Akeroyd, Emmanuel College, Cambridge; L. R. Barrett, Lincoln College, Oxford; T. K. Hanson, Oriel College, Oxford; and C. S. Windebank, University of London. Fellowships awarded to: L. M. Baxt, King's College, London; and T. A. Dent, St. Catharine's College, Cambridge. The Institute has also awarded 150 grants-in-aid to young men and women employed in chemical works to facilitate their further studies.

MEDICAL RESEARCH COUNCIL AWARDS

The Medical Research Council announces the following awards of travelling fellowships for the academic year 1936–37: Medical Research Council fellowships in medical science: J. T. Chesterman, H. E. Holling. Dorothy Temple Cross Research fellowships in tuberculosis: A. L. Jacobs, J. Smart, Dr. B. C. Thompson, V. C. Thompson. Rockefeller fellowship in psychiatry: Dr. J. H. Quastel.

Excavations at Tell Duweir, Palestine, 1935-36

AN exhibition of antiquities from Tell Duweir, the ancient Lachish, which have been obtained by the fourth expedition of the Wellcome Archæological Research Expedition to the Near East in 1935–36, opened at the Wellcome Research Institute, Euston Road, London, N.W.1, on July 9 and will remain open until the end of the month.

The excavations, which again were under the field direction of Mr. J. L. Starkey, were mainly directed to completing the clearance of a number of areas attacked in the course of previous seasons' work; but nevertheless, material of considerable archæological interest and importance was obtained. An interesting group of bronze objects, much crushed, came from a quarry on the saddle, which had partially collapsed in ancient times. These objects date from the early Middle Bronze Age of pre-Hyksos times, and among them were a kohl stick and mirror, of which the latter is the first example to be found at Tell Duweir.

A further clearance of the temple and its superimposed reconstructions made it clear that the essential plan of all three structures was identical, but that there had been a great expansion in the second temple. Further evidence was obtained pointing to the temple having been the seat of the cult of a triad of deities, of which one was female, and of affinities with the north. Below the floor of the second temple, a mass of pottery was found under the altar bench, which included a Late Helladic II goblet, dating at about 1450–1400 B.C. It is of buff paste with cream slip and has a painted band decoration showing an ivy leaf motif. This, from the point of view of the archæologist, is one of the most important finds of the season, as it dates more or less accurately, and links up a number of Palestinian finds.

Two sides, measuring eighty-five and seventy-five feet respectively, of a remarkable opening, apparently the entrance to a subterranean tunnel, have been cleared; and a clearance within the gate has revealed under the Persian level what was apparently the commercial quarter, with shops of a wine or oil seller, corn chandler and a weaver containing many of the appurtenances of their trades.

What proved, however, to be the most extensive and, in some ways, the most important discovery of the season, was made in the western valley in continuation of work begun two years ago. Here in a little-disturbed, small circular tomb lined with plaster was a collection of objects in number such as is rarely found in so small a space. From this were taken two hundred pots, of which fifty-three were types new to Tell Duweir. The most interesting was a censer, which in paste and finish recalls the famous Tell Duweir ewer on which was the inscription in the early Palestinian alphabetic script. This censer has lugs and a flat cover, on the upper side of which is an incised decoration with tree or plant motif in a hatched border, and on the under side a further example of the early script.

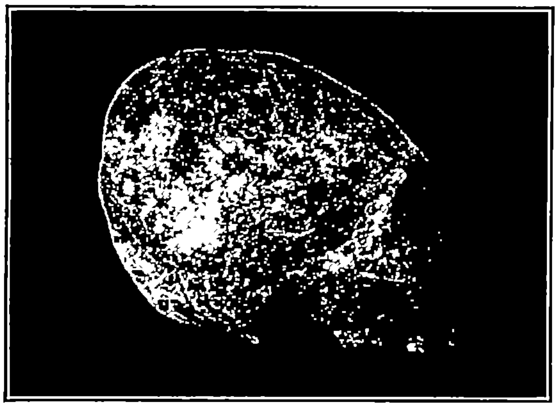

Photo *Ralph Richmond Brown*

FIG. 1. Artificially deformed skull from Tell Duweir. By courtesy of the Wellcome Archæological Research Expedition to the Near East.

The tomb itself, as is shown by a number of scarabs, dates from 1400 to 1300 B.C. or even 1275 B.C. Among the objects found are a long-tanged bronze dagger of Eighteenth Dynasty type, bronze lance and sporting arrow heads, and faience draughtsmen with plaques from the gaming board. In an adjacent larger sepulchral chamber the upper levels were a mass of rubbish, possibly from the Assyrian occupation, but the lower levels were composed of a conglomerate of human skeletal remains, of which the condition suggests that they may have been thrown through a hole in the roof—the door on the west side was found still blocked—as salvage from the buildings, when the city was sacked by Sennacherib in 701 B.C.

This skeletal material will afford valuable evidence of the physical characters of the early inhabitants of Palestine, especially as a remnant of the Canaanitish population may have lingered on at Lachish. Even more interesting is the fact that, in addition to head wounds, several of the skulls show a number of pathological conditions. Some have been artificially deformed (Fig. 1) and show such elongation in the occipital region that they resemble in shape the form of head familiar in the representations of Akhenaton; others have been trephined. Of these latter, two examples, instead of the more usual circular operation, have had a square section of bone, about an inch across, removed by sawing cuts, which intersect. This method, known in the Inca skulls from South America, is new to the ancient civilization of the Old World.

Educational Topics and Events

BELFAST.—Dr. W. H. McCrea, at present reader in mathematics in the University of London, has been appointed to the chair of mathematics in the Queen's University.

READING.—Under the will of the late Dr. Alfred Palmer, who died on May 20 last, the University has benefited by a valuable bequest of freehold property. It includes the main buildings of St. Andrew's Hall, the largest of the University's halls of residence for women students; a house known as "Summerbrook", near the main University site, which serves as the headquarters for the advisory officers of the Southern Agricultural Province; two houses used by Wessex Hall, another of the University's halls of residence for women students; four houses adjoining the main University site and used for general University purposes. The properties, which have hitherto been held on lease by the University, have been bequeathed free of duty.

Mr. Gerald E. H. Palmer has been elected a member of the University Council to fill the vacancy caused by the death of Dr. Alfred Palmer.

Mr. G. T. H. Kimble has been appointed lecturer in geography.

SHEFFIELD.—The following appointments have recently been made: Mr. N. S. Boulton, as lecturer in civil engineering; Mr. W. S. Milner (at present assistant lecturer), to be lecturer in electrical engineering; Mr. W. Skyrme Rees, as demonstrator in anatomy.

"ACADEMIC FREEDOM" continues to form the subject of much anxious discussion in America. The president of the University of California in a recent speech on "Problems of an American University" (*School and Society*, May 30) declared that more and more in the last year or two his university has felt, in common with others, the pressure of special groups, and he drew a lamentable picture of what the loss of freedom has meant to the universities of Germany, Italy and Russia. In these countries, "to-day there are no universities—only names and shells from which the spirit has departed. In each of these totalitarian States, universities have become the agents, the adjuncts, the subordinates of the State". In the same journal in which this speech is reported appears a letter from the president of the University of Minnesota referring to the increasing amount of control the Federal Government is exercising over the schools of the country, and to the necessity of keeping the schools and universities free from dictation by pressure groups and from regimentation by Government agencies. In the preceding issue, Prof. Thomas Woody, of the University of Pennsylvania, writes of the "hysterical efforts to create loyal citizens by legislative fiat" in recent attempts to pass laws to keep history "pure", and to regulate and restrict the teaching of science. "Even more serious in its ultimate possibilities for the suppression of freedom of the schools and colleges of the nation is the present obsession with respect to loyalty oaths for teachers". He proceeds to examine at length the grounds on which the requirement of such oaths (now prescribed in nineteen States) has been defended.

Science News a Century Ago

Sir Goldsworthy Gurney and his Steam Carriages

AMONG the successful pioneers of steam locomotion on roads was Sir Goldsworthy Gurney (1793–1875), the Cornish surgeon and inventor, known also for his invention of the oxy-hydrogen blowpipe and the limelight. It was while living in London that he turned his attention to steam-carriages, and in 1829 he went from London to Bath and back at a rate of fifteen miles an hour. On July 18, 1836, in the House of Lords, reference was made to the Steam-carriages Tolls Bill which had then passed through the committee stage. The Marquess of Salisbury, however, proposed it should be referred to a select committee for further consideration. In the course of his reply to this suggestion, the Earl of Radnor said: "Mr. Gurney, a gentleman of considerable talent, had directed all his attention to the construction of steam-carriages applicable to the road. He had given up a lucrative business, and applied himself wholly to that point. He had brought his invention to a state of great perfection; when all at once, a bill was introduced, not directly affecting his invention, but by a side-wind, entirely obstructing it, and laying such a tax on steam carriages as would completely defeat his object. His invention had been used without any accident whatever occurring; and this bill was intended merely to take off that burden which indirectly would operate greatly to the prejudice of Mr. Gurney".

Geology of the Island of Ascension

ON July 19, 1836, H.M.S. *Beagle* reached the island of Ascension, which Darwin compared to "a huge ship kept in first-rate order". Speaking of the geology of the island, he said: "The lava streams are covered with hummocks, and are rugged to a degree which, geologically speaking, is not of easy explanation. The intervening spaces are concealed with layers of pumice, ashes and volcanic tuff. . . . In several places I noticed volcanic bombs, that is, masses of lava which have been shot through the air whilst fluid, and have consequently assumed a spherical or pear-shape. Not only their external form, but, in several cases, their internal structure shows in a very curious manner that they have revolved in their aerial course". Describing more particularly one of these objects, he said: "The central part is coarsely cellular, the cells decreasing in size towards the exterior; where there is a shell-like case about the third of an inch in thickness, of compact stone, which again is overlaid by the outside crust of finely cellular lava. I think there can be little doubt, first, that the external crust cooled rapidly in the state in which we now see it; secondly, that the still fluid lava within, was packed by the centrifugal force, generated by the revolving of the bomb, against the external cooled crust, and so produced the solid shell of stone; and lastly, that the centrifugal force, by relieving the pressure in the more central parts of the bomb, allowed the heated vapours to expand their cells, thus forming the coarsely cellular mass of the centre".

The Herbarizing Dinner of the Society of Apothecaries

ON July 20, 1836, "the annual herbarizing dinner of the Society of Apothecaries took place . . . preceded by a lecture given at their hall by John Lindley, Ph.D., Professor of Botany to the Society. The noble President of the Medico-Botanical Society (Earl Stanhope), the Vice Presidents of the Linnean and Horticultural Societies, the President of the Royal College of Surgeons (Sir Astley Cooper), the ex-censors of the Royal College of Physicians, the Professors of Botany at the Metropolitan Schools of Medicine, and about 150 other gentlemen, attended on the occasion" (*The Times*).

Death of Jean-Félix-Adolphe Gambart

ON July 23, 1836, the French astronomer Jean-Félix-Adolphe Gambart, died at the early age of thirty-six years. He was born at Cette, in the Department of Hérault in May 1800. While quite a young boy he went to sea and then lived with his father, a teacher of navigation at Havre. His talents having attracted the attention of Alexis Bouvard (1767–1843), "the computing partner" of Laplace, he went to Paris, and in 1819 through Bouvard was made an assistant at the observatory at Marseilles of which Jean Louis Pons (1761–1831) was then the director. Pons having removed to Italy, Gambart in 1822 was made director of the Observatory, and though supplied with somewhat inferior instruments, in the course of eleven or twelve years discovered thirteen comets, including Biela's comet, first seen on February 17, 1836. In recognition of his work he was made a member of the Paris Academy of Sciences. Recalled to Paris in 1834 for work at the Bureau des Longitudes, his promising career was cut short by consumption.

Medical Statistics

IN his retrospective address delivered at the third anniversary meeting on July 23, 1835, of the Provincial Medical and Surgical Association held at Oxford, Dr. J. C. Prichard, F.R.S., senior physician to the Bristol Infirmary, said that there could be no method of research more in harmony with the philosophical character of the present age than inquiries which were termed statistical. There was no investigation more calculated to extend our knowledge, on a great scale, both of the physical and moral condition of mankind without opening the door to anything discursive or imaginary. Statistical researches were likely to afford the most satisfactory solution of difficult problems which had hitherto been thought to lie within the realm of speculation; and our mistrust of the speculative way of treating such questions was increased by the remark that in almost every inquiry submitted to the test of accurate numerical calculations, the result had turned out in direct opposition to what appeared to be the most probable conjecture. Who, for example, would ever have imagined that human life would not exhibit a larger average duration in the genial climate of Greece, Italy and other countries on the northern coast of the Mediterranean . . . than on the inclement shores of the Baltic and Frozen Ocean? It had been demonstrated, however, in a memoir drawn up with great accuracy of research and presented to the Academy of Sciences that human life had double the duration, or that men lived on the average twice as many years in the *Ultima Thule*—the bleak Iceland and on the Norwegian coast—as in the delightful plains of Campania and in the valleys of Andalusia.—(*Trans. Prov. Med. and Surg. Assoc.*, 1836.)

Societies and Academies

Paris

Academy of Sciences, June 8 (*C.R.*, 202, 1881–1952).

André Blondel : A radioelectric method for the calculation of transient régimes.

Georges Claude : The presence of gold in sea-water. An application of the method suggested by Glazunov to 168 cubic metres of sea-water taken off the coast of California. The gold was too small to be determined, and was less than 0·1 mgm. per cubic metre.

Dimitri Riabouchinsky : The paradox of d'Alembert at supersonic velocities.

Edgar Baticle : The problem of collisions.

Salvatore Cherubino : Holomorph functions of a matrix.

Léon Pomey : The general harmonic properties of unicursal involutions of order *n*.

René Lagrange : An inequality of Hobson.

Alexandre Weinstein : The equations of the vibrations of a fixed-in plate.

Mlle. Nina Baby : The Diophantic nature of the unicity problem of the trigonometrical development.

Jean Hely : The application of a synthetic theory of relativity to the orbits of the planets.

Charles Platrier : The problem of Barré de Saint-Venant *in perfectly flexible homogeneous* media.

Imai-Isao : The stability of the double row of vortices in a rectilinear canal.

A. Toussaint and S. Pivko : The influence of the limitations of the fluid sheet on the aerodynamic characteristics of supporting wings. Experimental verifications.

Bernard Kwal : Dirac's equation and the theory of the electromagnetic field.

Marcel Pauthenier and Mme. Marguerite Moreau-Hanot : An ionic generator giving a million volts. Details of the practical realization of an apparatus based on a theory previously described.

Jean Granier : *An important cause of error in* the measurement of capacities by the ballistic method. In measuring condensers of high capacity, either the variations of period must be taken into account or less sensitive galvanometers, heavily shunted and with a high moment of inertia, must be used.

Jean Lecomte : Infra-red absorption spectra and the modes of vibration of organic compounds. From the study of compounds of the types $X.CH_2CH_2.Y$ and $X.CH_2.CH_2.CH_2.Y$, the numerous absorption bands found in nearly all the spectra for frequencies lower than 1,100 $cm.^{-1}$, can be explained only if the existence of several molecular forms is admitted.

Jean Reboul : The action exerted by ordinary metals on the photographic plate and on the electrometer. The study of the ionization of the atmosphere surrounding ordinary metals, suggests that there is an emission by these metals of an X-radiation of small quantum. The action on the photographic plate is not parallel to the ionization, and Russell's suggestion of the formation of hydrogen peroxide may apply in some cases.

Pierre Auger and Albert Rosenberg : The properties of the cosmic corpuscles of the penetrating group.

Hormisdas : A new colorimeter for determinations in series.

Horia Hulubei : Researches relating to eleme No. 87. The results of experiments given are co sistent with the presence of element 87 in extreme small quantity in pollucite.

Clément Courty : The diamagnetism of thi cyanates and of the ion Cu^+.

Marc Tiffeneau and Mlle. B. Tchoubar : T differences of behaviour of the *cis* and *trans* cycl hexanediols during their dehydration.

Albert Kirrmann and Pierre Renn : T mechanism of the allyl transposition.

François Dupré la Tour : Inversion of pol morphism in the series of normal saturated diacic

Georges Rempp : A differential frigorimeter. simple instrument for measuring the mean veloci of the air, possessing a greater thermal inertia th the hot wire anemometer.

Etienne Fœx and Maurice Lansade : Tl *pathogenic action of a bacterium isolated from pota* tubers. The characters of this organism agree wi those of *Bacterium xanthochlorum*. Studies have bee made of its pathogenic action on potato tubers ar buds, leaves of Solanaceæ and Leguminoseæ and c seeds of Solanaceæ.

Paul Riou and Joachim Delorme : The lea *values in maple and cane sugars.* From a determin tion of the lead values of cane sugars from variou sources, it is concluded that this value can give r indication of the adulteration of maple sugar wit raw cane sugar.

Albert Raynaud : The heterochromosomes c mulot.

Robert Brunet and Antoine Jullien : Tl architectural characteristics of the heart in tw marine lamellibranchs, *Ostrea edulis* and *Venus gallin*

Mlle. Marie Louise Rocco : The presence c allantoinase in insects. The aerial arthropods, lik the aquatic arthropods, contain the enzyme allar toinase.

Francis Rathery, André Choay and Pierre D Traverse : Isolation from the mucous membrane c the jejunum of a principle reducing glycæmia.

Maurice Doladilhe and Mlle. Marguerit Michel : Contribution to the study of the alex properties of protein C.

The Planning of Human Life

THERE must be many among the ranks of scientific workers who, from time to time, have been alarmed at the consequences which might attend the further extensions of the restrictions on freedom of scientific thought and investigation already imposed in various European countries and elsewhere, or the continued prostitution of scientific effort on an ever-growing scale on preparations for war. Others have been disturbed at the paradox presented by the heavy incidence of unemployment and distress in a world which science has already endowed with resources undreamed of scarcely a generation ago.

Few, however, as yet have concerned themselves with the underlying causes of the present unhappy and threatening position, and Prof. L. T. Hogben's recently delivered Conway Memorial Lecture* is accordingly the more welcome because of its stimulating challenge to creative thought on new lines about social life, and therefore about politics and economics. His outspoken comments were much more than a plea for a biological basis for social and political thought. The whole lecture was a call for a courageous linking of knowledge and action and seeing life as a whole, in which scientific method finds its use in arriving at new knowledge and solving practical problems, and action is seen as an essential if life is to be achieved in its fullness.

At a time when what Prof. Hogben describes as the retreat from reason is at full flood, it is refreshing and inspiring to meet such a frank exposure of past failures and an exposition of new lines of advance which may yet retrieve the position. Science could desire no better apologist, and even those who are unconvinced by Prof. Hogben's arguments can scarcely fail to admit the impossibility of tame acquiescence in the present position, unless we are content to see the very spirit of science slowly choked to death.

The retreat from reason, the growing dominance of prejudice and ignorance in public affairs, is attributed to neglect of education. The most expensive products of the educational system of Western civilization are really uneducated for life in the present world; and democracy is becoming a farce, because this expensively educated class, from which Capital and Labour attract the leaders and administrators, is increasingly at the mercy of technical experts whose own training involves no recognition of their social responsibilities.

The training of the statesman or the man of letters gives him no prevision of the technical forces which are shaping the society in which he lives: the education of the scientific worker and the technician may well leave him indifferent to the social consequences of his own activities. If we are to arrest the retreat from reason, we must devise an education which will give us representatives who can co-operate intelligently with technical experts in constructive social enterprise, and teach us how to choose them.

This is the first task, and upon it Prof. Hogben makes many shrewd remarks. He questions, for example, whether we now have as large a proportion of scientific men actively interested in politics as there were at the time of Joseph Priestley and Benjamin Franklin. Moreover, a nation cannot expect men of science to help in times of difficulty unless it elects representatives who know enough about the scope of technical possibilities to enlist their skill. If, however, a man is not politically educated unless he has some knowledge of natural science, the teaching of natural science has still to be adapted to the requirements of a rational curriculum of humanistic studies. We need more science, but not more science as it is taught for vocational purposes.

---

* The Retreat from Reason By Lancelot Hogben. (Conway Memorial Lecture delivered at Conway Hall, Red Lion Square, W.C.1, on May 20, 1936.) Pp. xi+83. (London: Watts and Co., 1936.) Paper, 1s. net; cloth, 2s. net.

The real reason why science must be an important part of education is that intelligent citizenship is no longer possible unless we understand the place of science in the everyday life of everybody. Attention is directed to the closer co-operation between the teaching of history and of natural science in school and university alike which this demands. Co-operation between the historian and the man of science is, in fact, required to make education socially fertile; and the social value and interest of scientific teaching could be further enhanced if the relation of growing knowledge to the developing social needs of mankind were emphasized in the teaching of natural science.

The interest which the British Association has taken in the relation of scientific work to social questions in recent years indicates that Prof. Hogben is not alone in many of his arguments. To reinstate confidence in human reason, however, the teaching of history in such a way as to produce citizens capable of realizing the part which advancing scientific knowledge has played in the material progress of mankind is only one factor. The teacher of science can and should let his pupils understand from the beginning what are the responsibilities in everyday life which scientific discipline lays on all those who have once submitted to it, but that in itself it is not sufficient to secure action in discharge of those responsibilities.

No single point is so strongly stressed by Prof. Hogben as this of action. Quoting T. H. Huxley that "the great end of life is not knowledge but action", he suggests that the divorce of thought from action is one of the prime causes of our present difficulties. The pursuit of the social sciences has not been closely linked with the development of new institutions and the discovery of new modes of social living; and unless knowledge is encouraged as a means to action instead of as a means to more knowledge, we are unlikely to regain control over events and reap the possibilities of plenty which science has put within our reach.

Lack of familiarity with scientific matters has been an important factor in the crumbling away of our social traditions under the stress of economic disaster, but we can only stabilize the new social pattern by securing that action is related to knowledge and that the new knowledge to be acquired is pursued in relation to a definite plan of action. We have still to discover the laws of change of human nature, and until in this way we have arrived at a science of human nature, it is idle to expect the public needs of a progressive society to harmonize with the private needs of human nature.

Nor is this all. We are blundering on the threshold of an era of technical changes, the consequences of which can scarcely yet be predicted even by the technical man, let alone visualized by the average administrator. The introduction of the new plastics in building, housing and clothing, the replacement of heavy metals by light metal alloys in constructional work, changes in power production, increased productivity of pastures, field crops and live-stock through the use of fertilizers, soil control, genetic selection and control of pests, hold revolutionary consequences which demand study and reconstruction in all directions.

Equally we are entering on an era of biological inventions, with new possibilities of bodily and mental health if our resources are planned intelligently with the object of satisfying real human needs. A rational basis for human society involves planned consumption to ensure the maintenance of population. The only rational basis for such planning is scientific research into the character of fundamental human requirements and the national resources available for gratifying them. We could then formulate a policy and programme of national reconstruction which would command the irresistible support of the wage-earning and salaried classes, and should be above the squabbles of party politics as we have known them. When the existence of a universal need is recognized, the problem of satisfying it is a joint matter for economists and technicians.

A science of preventive social medicine must have as its first concern the satisfaction of known universal needs, and psychologists should be encouraged to explore the distribution of human capabilities in relation to the idiosyncratic requirements of individual human beings. Prof. Hogben, in fact, boldly calls for an inquiry into the wealth of nations on entirely new lines, including the utilization of social personnel and the study of the social resources available for canalizing a common will to increase the wealth of nations. In regard to the first, the studies of recruitment he suggests, including the large-scale testing of Parliamentary candidates for vocational aptitudes on similar lines to those worked out for various purposes by the National Institute of Industrial Psychology, though likely to meet with ridicule at the moment, would represent a real contribution to political science and society.

The picture which is thus presented to us does not minimize the dangers of the present situation ; rather it reminds us once more that the way of escape is still open if we choose to take it. The planning of human life, in accordance with growing knowledge of the nature of fundamental human needs and the natural forces now at our disposal if we use them intelligently, is not a task which can be or will be undertaken by political leaders, who have little regard for the nature of human needs and are unfamiliar with the technical resources which can be mobilized by intelligent organization.

The scientific worker, therefore, cannot evade his share of responsibility. He, at least, must lend his aid if anyone is to take stock of the resources of knowledge for social betterment. He as no other can lead the return to the exposition of the simple and well-tried truths of science, and resist the exploitation of speculative, socially insignificant and unproved hypotheses before mystified audiences. Also he can lend his support both to the re-orientation of scientific research in accordance with a real plan of social research, and to the political and social forces necessary to compel action along the lines of knowledge rather than those of prejudice.

Enzyme Studies

Ergebnisse der Enzymforschung
Herausgegeben von F. F. Nord und R. Weidenhagen. Band 5. Pp. xi + 378. (Leipzig : Akademische Verlagsgesellschaft m.b.H., 1936.) 30 gold marks.

THESE "Ergebnisse" once more contain valuable summaries of selected sections in the continually expanding field of biochemistry included under the term 'enzymes'. The contributions are as international as ever, but only the minority are from German laboratories : it is an interesting question whether this denotes a falling off in scientific activity there under present political conditions.

Prof. Alex. McKenzie of Dundee gives the complete story of asymmetric synthesis, a subject to which he has devoted his energies and which has not been monographed as yet. Very opportune is an account written by Folley and Kay, fifty-four pages in length, of the phosphatases, since the substrates on which they act, the phosphoric esters, hold a key position in many of the processes taking place in living organisms : thus they are concerned in alcoholic fermentation, muscular contraction, bone formation and lactation, whilst the many phospho-organic compounds in living matter are probably all dependent on the activity of phosphatases. At present there is no real understanding of the true role of these enzymes, but much progress can be reported in the accumulation of facts : the summary should help to arouse fresh interest in the subject. It is followed by an article on lecithase, the mixture of enzymes which hydrolyse lecithin in a variety of ways : this is from Milan and is written by Messrs. Belfanti, Contardi and Ercoli. No less than seven different enzymes take part in the simplification of lecithin by a series of steps which thus afford a very interesting biological problem.

Another summary, dealing with a problem which is still unsolved despite its importance, is that on the biochemical synthesis of fats, from the pen of Dr. Smedley Maclean. We know that the pig in particular is able to effect the transformation with ease, but neither the site in the body where it happens, nor the nature of the first products of the synthesis, has been determined. The author inclines to the theory, for which there is some experimental support, that pyruvic acid is the intermediate stage, rather than accepting the alternative formation of fat direct from hexose or through acetaldehyde.

There is a stimulating article on proteases by Grassmann and Schneider, of Dresden. Since Northrop has been so successful in obtaining some of these enzymes in the crystalline state, enhanced interest is attached to their behaviour. It is now possible to lay down exact conditions for the structure of the substrate favourable for the action of the peptidases, and the same applies to the carboxy-polypeptidases, which require also a free carboxyl group in the substrate. Progress is also to be recorded in the identification of some of the active groups in these substances.

A group of enzymes, of which the knowledge is vague, are those that hydrolyze the pectins : a useful summary about them is provided by Kertesz, of Geneva, N.Y. Pectinase appears to be a complex of enzymes containing at least a polygalacturonase and a pectin methoxylase, the former being a glycosidase and the latter an esterase: other constituents appear to be able to split off arabinose or galactose from the pectin complex. This is obviously a field requiring much further investigation.

Müller, of Copenhagen, describes an oxidase prepared from *Aspergillus* or *Penicillium*, which is able to oxidize glucose to gluconic acid with atmospheric oxygen: the significance of this reaction in the economy of these fungi is discussed.

Space considerations allow only of reference to one other review, namely, that on chlorophyll photosynthesis, from the pen of Robert Emerson of Pasadena. The review is opportune, for the subject continues to be a very difficult one, and in spite of a lot of work there has been no great progress in it during the last decade. At least the behaviour of enzymes towards carbon dioxide is being studied energetically, whilst a great deal more is known about chlorophyll.

The items which have been picked out for comment serve to indicate the value of the book: the editors once more deserve thanks for providing such stimulating fare. E. F. A.

History of Medicine

(6) American Medicine

By Dr. Henry E. Sigerist. Translated by Hildegard Nagel. Pp. 316+30 plates. (New York: W. W. Norton and Co., Inc.; London: Oxford University Press, 1934.) 16*s*. net.

(1) THE work on medicine in the Middle Ages by Dr. David Riesman, professor of the history of medicine in the University of Pennsylvania, contains an admirably comprehensive study of the medical aspects of an age which until recently had received comparatively little attention. As Dr. Riesman points out, we are in the first place indebted to medieval medicine for the preservation of the writings of the Greeks, Romans, Arabians and Jews, without which progress in medicine would never have taken place. As regards Arabian medicine, he judiciously remarks that it is yet too early to pass a final judgment in view of the probable existence of many undeciphered texts, but he brings forward in its favour the preservation of many texts, many chemical discoveries, good advice concerning diet, a clear account of many diseases, and a considerable number of plant remedies.

The work of the universities, the foundation of which Dr. Riesman regards as probably the greatest achievement of the Middle Ages, next receives attention, special chapters being devoted to the medical personalities and studies at Montpellier, Bologna, Padua, Paris and Oxford and Cambridge respectively.

Considerable attention, of course, is given to the description of the various diseases prevalent in the Middle Ages, of which the most important were plague, leprosy, sweating sickness, St. Anthony's fire, the King's Evil and epilepsy. The vexed question as to the existence of syphilis in medieval times is fully discussed, the author being of opinion that it is not yet possible to say definitely whether the disease was imported from America or not. Other aspects of medieval medicine considered are alchemy, the hospitals of the period, medicine and the guilds, medical text-books in use, hygiene and sanitation, and the lay attitude towards the medical profession with special reference to the unkindly criticisms of Petrarch and Chaucer.

In conclusion, Dr. Riesman points out that the greatest difference between modern times and the Middle Ages in medicine, as in all sciences, is the objective experimental method characteristic of modern times. The text is liberally interspersed with portraits and other illustrations.

(2) In his little book on Talmudic medicine, which is based on the works of Julius Preuss, I. L. Katzenelsohn and M. Pearman, Dr. J. Snowman describes the medical conceptions current among the Jews during the Talmudic period, that is, from A.D. 200 to 600. An excellent account is given of the Talmudic theories as to the causation and cure of diseases, contemporary anatomy and physiology, and the progress made in the various branches of medicine.

The descriptions of superficial anatomy in the Talmud are remarkably accurate, but owing to the absence of dissection little could be learnt about the internal organs, though fanciful views were expressed as to their functions. The medical diseases mentioned in the Talmud include acute intestinal disorders probably due to dysentery, and leprosy, quinsy, cold in the head, worms and headaches, while the surgical disorders consist of superficial wounds, stone in the bladder, abscesses, burns and scalds, bites of mad dogs, snake-bites and fractures and dislocations. A special chapter is devoted to the minor operations of ritual circumcision and venesection, which was used for therapeutic and hygienic purposes.

As regards gynæcology and obstetrics, the diseases of women mentioned in the Talmud are mainly connected with uterine hæmorrhage. Difficult labour is frequently noted; sacrifice of the infant and Cæsarean section appear to have been practised. Diseases of the eye are frequently mentioned, especially cataract and corneal opacities.

The rabbis' knowledge of comparative anatomy, though gained only from the study of certain cattle, sheep and poultry, seems to have been remarkably extensive, being concerned with changes in the lungs, brain, heart, liver, spine, stomach, gall-bladder and intestines.

(3) In their work on medical practitioners in the diocese of London 1529–1725, Messrs. J. Harvey Bloom and R. Rutson James have compiled an annotated list drawn from various sources of those licensed to practise under the Act of 3 Henry VIII, c. II in the diocese of London. The book does not contain the names of all the practitioners in the diocese, as those licensed by the Royal College of Physicians as well as some surgeons and barber surgeons are not included. The Act laid down that no person within the City of London or within seven miles of the same should take upon himself to practise as a physician or surgeon unless he had been first examined, approved and admitted by the Bishop of London or by the Dean of St. Paul's, assisted by doctors of physic and other expert persons in the faculty of surgery. Of the examiners, the only well-known names that have been preserved are those of Sir Hans Sloane, president of the Royal Society and of the Royal College of Physicians, John Evelyn the diarist, and the infamous Titus Oates.

The list contains in all 360 names, of which 184 have their documents preserved at Somerset House and 176 in the registry of the Bishop of London. The most eminent licencees in the list are William Clowes (1540–1604), the famous Elizabethan surgeon attached to St. Bartholomew's Hospital; Charles Bernard (1656–1710), Sergeant-Surgeon to Queen Anne, surgeon to St. Bartholomew's Hospital and owner of a fine library; Ambrose Dickins (1687–1747), surgeon to Westminster and St. George's Hospitals and Master of the Barber Surgeons' Company; and William Cheselden (1688–1752), surgeon to St. Thomas's and St. George's Hospitals and famous for his operations for stone and cataract. The Act was never repealed, but died a natural death through lack of applicants.

(4) Smollett's essay on the external use of water, which was originally published in 1752, is preceded by an introduction by Mr. Claude E. Jones, who remarks that Smollett's writings are of interest to the student of medical history for two reasons; first on account of his small ventures in the field of medicine proper, of which the present essay is an example, and secondly for the vast number of medical pictures and comments scattered through his other works.

The present essay purports to be a letter addressed to Dr** "on the external use of water with particular remarks upon the present method of using the mineral waters at Bath in Somersetshire, and a plan for rendering them more safe, agreeable and efficacious". After a brief account of the value of the internal use of pure water, Smollett describes its employment in the form of foot-baths, universal baths and fomentations in the treatment of various disorders. In conclusion, he directs attention to certain inconveniences attending the use of the waters at Bath, such as promiscuous admission of diseased persons of all ages, sexes and conditions into an open bath, the confinement of their use to the most severe seasons of the year, and the lack of attendants and proper conveyances, and draws up a series of proposals to remedy these inconveniences.

(5) The history of the Middlesex Hospital Medical School is admirably told by Dr. H. Campbell Thomson, consulting physician to the Department for Nervous Diseases at the Hospital, and from 1908 until 1919 dean of the Medical School. Although the school was not founded until 1835, teaching in the hospital began shortly after the hospital was established in 1745. The inaugural address on October 1, 1835, when the medical school was formally opened, was delivered by Sir Charles Bell, the eminent anatomist and artist, and one of the three surgeons to the hospital. It

is noteworthy that five of his colleagues on the staff were, like himself, fellows of the Royal Society, the most eminent of them being Sir Thomas Watson, the senior physician and professor of medicine in the School, whose work on the principles and practice of physic is a medical classic.

Since that time, the Medical School has had a number of famous men on the staff, the most remarkable co-existence of celebrities at one time being the triumvirate in 1906 consisting of Sir Henry Morris, president of the Royal College of Surgeons, Sir Richard Douglas Powell, president of the Royal College of Physicians, and Sir James Kingston Fowler, dean of the Faculty of Medicine of the University of London.

Two scientific institutes connected with the School deserve special mention, namely, the Bland-Sutton Institute of Pathology opened in 1914, and the Courtauld Institute of Biochemistry opened in 1928, where there are always a number of research workers from Europe and the United States.

(6) In the excellent English translation by Miss Hildegard Nagel of his work on American medicine, Dr. Henry E. Sigerist, professor of the history of medicine at Johns Hopkins University, who had formerly held the corresponding chair at Leipzig, has given a lively account of the development of American medicine, from the earliest times until the present day as seen by an unprejudiced and sympathetic observer.

The book contains an interesting account of primitive medicine in North America, followed by a description of medicine in the colonial period, biographical sketches of medical pioneers in the United States from John Morgan and Benjamin Rush in the eighteenth century down to Billings and Osler in our own time, the present condition of medical education with special reference to Johns Hopkins University, where attention is focused on science and research, the organization of hospitals and nursing, public health work including campaigns against infectious diseases, maternity and child welfare, mental hygiene and various scientific institutions connected with medical clinics.

Dr. Sigerist rightly claims that whereas fifty years ago American schools counted for nothing in world medicine, to-day the standard of education equals that of most European countries and in many places and in some points is superior.

Theory and Practice of Electrochemistry

(1) Electrolytic Oxidation and Reduction: Inorganic and Organic. By Dr. S. Glasstone and Dr. A. Hickling. (Monographs on Applied Chemistry, Vol. 9.) Pp. ix+420. (London: Chapman and Hall, Ltd., 1935.) 25*s*. net.

(2) Principles of Experimental and Theoretical Electrochemistry
By Prof. Malcolm Dole. (International Chemical Series.) Pp. xiii+549. (New York and London: McGraw-Hill Book Co., Inc., 1935.) 30*s*. net.

(3) Principles and Applications of Electrochemistry
By Prof. H. Jermain Creighton. In 2 vols. Vol. 1: Principles. Third Edition, revised and enlarged. Pp. xviii+502. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1935.) 20*s*. net.

(4) Principles and Applications of Electrochemistry
By Prof. W. A. Koehler. In 2 vols. Vol. 2: Applications. Pp. xiv+545. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1935.) 25*s*. net.

SOME sections of the broad science of chemistry are purely theoretical, others are essentially practical, but electrochemistry in its modern developments combines the two aspects. The appreciation of its principles demands an intensive knowledge of mathematics and thermodynamics; the application of those principles to industrial purposes is of fundamental importance, both on the inorganic and on the organic sides. No Chancellor of the Exchequer needs to ask to-day, as Gladstone did: "What's the use of it?"; he has long ago taken advantage of Faraday's reply to the question: "Why, sir, there is every probability that you will soon be able to tax it!"

(1) The monograph by Drs. Glasstone and Hickling illustrates to an unusual degree the close intermingling of present-day electrochemical theory and practice. As the preface states, purely empirical methods are no longer satisfactory in the control of industrial processes, and success in such operations can only follow from an understanding of the fundamental principles involved.

The basic theory of the subject is clearly presented in this book, and a multitude of practical illustrations discussed in detail. Full references to scientific and patent literature are appended at the end of each chapter, and the hope of the authors that "the book will be of value both to research workers and to technical chemists interested in the enormous possibilities of electrolytic methods" will no doubt be amply fulfilled. The book is one to be highly recommended.

(2) The volume by Prof. Dole, of Northwestern University, Illinois, is more restricted in its scope, dealing as it does only with the theoretical principles of electrochemistry. These principles, however, are introduced throughout from an experimental angle, so that in spite of the fact that the main stress of the book is upon the interpretation of electrochemical phenomena, the student who has conscientiously studied each chapter should be well equipped to put the knowledge acquired to practical use if necessary. The book constitutes a serviceable text for honours students specializing in electrochemistry and for Ph.D. research workers in this branch of the subject.

(3) The fact that Prof. Creighton's "Principles of Electrochemistry" has now reached the stage of a third edition is evidence of its popularity and merit. The treatment is elementary but thorough, and furnishes a most readable introduction for the student of electrochemical theory. In order to bring certain topics into harmony with recent advances, a great many portions of the second edition have been rewritten and new subject matter has been added. The problems inserted at the end of nearly every chapter and the numerous references to original papers add materially to the value of the book.

(4) "Applications of Electrochemistry", by Prof. Koehler, forms a companion volume to Creighton's "Principles". It is intended for two classes of readers: students in universities, colleges and technical schools for use as a textbook; and persons connected with the industry for use as a reference work. The difficult problem of making the book sufficiently complete and up-to-date without at the same time making it too voluminous for academic purposes has been very successfully met, and the impressive list of experts to whom the author makes acknowledgment for assistance and suggestions bears witness to his assiduity in ensuring accuracy in each section of the field covered.

Practically every point of importance in inorganic electrochemical industry is presented in a clear and compact manner, and the presentation is assisted materially by a large number of plates, diagrams and tables. Organic electrochemistry, presumably for reasons of space, is scarcely touched. A third volume of the series, treating this subject in the same admirable style, would be warmly welcomed. JAMES KENDALL.

Forests and Flora of British Honduras

The Forests and Flora of British Honduras
By Paul C. Standley and Prof. Samuel J. Record, in cooperation with the Conservator of Forests and the Agricultural Officer of the Colony. (Botanical Series, Vol. 12, Publication 350.) Pp. 432+16 plates. (Chicago: Field Museum of Natural History, 1936.)

FOLLOWING a short introduction on the geography, soils, climate, agriculture and forest products of British Honduras, the remainder of this substantial volume is divided into two parts, entitled respectively "The Forests" and "The Flora". In Part 1, which occupies about thirty pages, and is contributed by Prof. Record, a description is given of the forests, with a short history of the same, and a reference to and description of most of the timbers of economic importance, including uses as timber and also for pulp, with an interesting account of the Chicle gum industry. Throughout the remainder of the work Prof. Record has also contributed a description of the different woods wherever they are named, and he states that "the wood descriptions are short because all of the more important species have been covered more fully in 'Timbers of Tropical America' or in special articles in *Tropical Woods*".

Part 2, comprising the whole catalogue of the trees and shrubs of British Honduras, is the work of Mr. Standley, no doubt greatly assisted by the knowledge acquired by Prof. Record, who "began about ten years ago to compile a list of all of the available scientific and local names of the woody plants of the Colony". This splendid production is of first importance as presenting an authoritative work on a much needed subject, and comes at a timely moment, because—perhaps for the first time—a vigorous reorganization of the Colony's timber production and conservation is at work.

Prof. Record points out that "although British Honduras has been a timber-producing country for 250 years, systematic forestry was started only in 1922 with the formation of the Forest Department". This Department is vested in a Forest Trust with the Governor as chairman, and the policy laid down includes an excellent programme which should very soon yield many results, not the least of which is to find a market for some of the useful secondary woods. The work provides a full list, enabling the timber expert to trace the vernacular names to the correct identification of the botanical types, and provides the same advantages to the large number of people who are enthusiastic collectors of useful and ornamental flowering shrubs.

A painstaking and conscientiously accurate description is given of the measurement of the trees, leaves, flowers and fruit, together with the districts in which they abound.

The history of this tropical country is full of romance and interest. Why the Maya peoples settled there, or whence they came seems to be undecided. In the beginning, their fight against Nature and the jungle must have been very severe, but at last they succeeded and established their cities. Then again Nature reasserted herself, and in course of time turned them out.

Gann and Thompson say:

> "those cities which were ill situated, from an agricultural point of view, would naturally be the first deserted, while the cities in the fertile lands of north-eastern Peten would be amongst the last.
>
> "Whatever the cause, it is certain that by the third Katun of Bactun 10, or 629 A.D., the whole of the Old Empire was almost completely abandoned, and remained so for the next seven or eight centuries, when reforestation of the lands enabled at least a part of the descendants of the original dwellers to return to the home of their ancestors."

The same authors inform us that it took 250 years for the Maya to evacuate the land. They state that the reason for the evacuation is not known, but they mention seven possible reasons, of which the sixth is "exhaustion of the soil". The other reasons are: "1. National decadence. 2. Epidemic disease. 3. Earthquakes. 4. War, internecine or foreign, or both combined. 5. Climatic changes. 7. Religious or superstitious reasons."

The practice followed by almost all primitive peoples was to cut down the trees and shrubs over one area, and move on after a year or two, repeating the same process in another, which must at last have rendered the whole country barren of trees, so that erosion of the soil would have followed in the same way as in other countries. There seems to be little doubt, therefore, that the sixth reason referred to above, namely, "exhaustion of the soil", was the cause of the final evacuation.

The romance of this country did not finish with the departure of the Maya. The story of the early British voyagers who visited these far distant countries is fairly well known. Prof. Record informs us that:

> "It was at one time the practice of the class of privateers . . . cruising against Spanish traders to set fire to all vessels they captured which might be laden with Logwood, having first stripped them of everything valuable.
>
> "But it so happened that a Captain James, the master of a letter of marque, having captured a Spanish vessel the cargo of which consisted of this wood, brought the ship and cargo into the Port of London. On endeavouring to dispose of the latter he was gratified as well as surprised to find for it a ready sale at an enormous price per ton. The crew, who had used up a portion of the precious freight to burn in the galley fire, had little idea that they were using fuel at a hundred pounds per ton during the voyage."

No less romance is attached to the beginning of the trade in mahogany, which is supposed to have begun about 1725. A little later, in 1786, a treaty was made between Great Britain and Spain, which gave the right to British settlers to cut wood "not excepting even mahogany".

Having regard to the importance and value of this colony, it seems incredible that a recognized forestry service should have been started only in 1922, but with the competent activities of the present Governor, and the Conservator of Forests, good results may confidently be expected. There can be no stronger indication of its importance than the interest shown by the two very well-known authors of the present work—Samuel J. Record and Paul C. Standley. Prof. Record had already provided generous contributions to our knowledge of forests and their products, and this new book comes at a most opportune moment.

ALEXANDER L. HOWARD

Das Tierreich:

eine Zusammenstellung und Kennzeichnung der rezenten Tierformen. Gegründet von der Deutschen Zoologischen Gesellschaft. Im Auftrage der Preussischen Akademie der Wissenschaften zu Berlin. Lief. 65: Lepidoptera—Parnassiidæ pars 2 (subfam. Parnassiinæ). Bearbeitet von Felix Bryk. Pp. li + 790. (Berlin und Leipzig: Walter de Gruyter und Co., 1935.) n.p.

THE contents of this extensive work are embodied in the title. It monographs the genera and species of 'Apollo' butterflies forming the subfamily Parnassiinæ together with their numerous forms of subspecies. In each case, the synonomy is given, followed by a description of the species and form concerned, its distribution and the location of the type specimens. It is profusely illustrated by means of 698 text-figures of the various species, together with structural details of a diagnostic character. The extraordinary range of forms into which the various species are divisible has made the genus a specialized study among lepidopterists. In the case of *P. apollo*, for example, the index alone of the forms of this species runs to five pages of double columns. A detailed and authoritative work of this kind is likely to remain a standard for a number of years.

The Subject Index to Periodicals, 1935

Pp. xiii+235. (London: The Library Association, 1936.) 70*s*.

WITH this issue the "Subject Index to Periodicals" completes twenty years of existence, the first volume published being for the year 1915. The volume for 1935 appeared only five months after the close of the year covered. The general editor, Mr. T. Rowland Powel, his staff and the voluntary contributors are to be congratulated on the rapidity with which the work has been carried out. The Subject Index for 1935 comprises entries of about 26,000 articles selected from 590 periodicals. Of these periodicals 540 are English and American, 27 French and Belgian, 21 German, and 2 Italian. The articles selected are arranged under headings such as "Light", "Lighting", "Lightning", etc., but under each heading the order is that of authors' names.

The subjects selected for indexing are by no means confined to science, but cover a wide range. Verse and fiction are excluded. With few exceptions, no attempt has been made to index periodicals already indexed in the following: *Agricultural Index, Engineering Index, Engineering Abstracts, Index Medicus, Journal of the Society of Dyers and Colorists, Photographic Abstracts, Revue de Géologie, Royal Meteorological Society Bibliography, Science Abstracts, Textile Institute Journal.*

All workers in science value these Subject Indexes, and appreciate the care and efficiency which, under the auspices of the Library Association, have been devoted to their production. It is probable that many a valuable paper, published in a journal that is little read, is here introduced to a much larger world.

Pheretima (The Indian Earthworm)

By Prof. Karm Narayan Bahl. (The Indian Zoological Memoirs on Indian Animal Types, 1.) Second edition, revised and enlarged. Pp. x+85. (Lucknow: Lucknow Publishing House, 1936.) 1.8 rupees.

PROF. BAHL, the author of the memoir under notice, is also the general editor of this useful series. It is ten years since the first edition was published, and the relevant work done in the interval has been incorporated. The book has been thoroughly revised and to some extent rearranged. It is printed upon a more satisfactory paper, which does better justice to the illustrations. Five of the figures of the first edition have been omitted, nine new ones inserted and several have been redrawn, resulting in a distinct improvement. The brief account of the development has been omitted but an interesting new chapter on the receptor organs has been put in. The old chapter on habits and distribution has been rewritten and extended, and removed to near the end as "Bionomics, Distribution and Relationships".

The memoir was good when first issued and its usefulness is shown by the demand for a second edition. In its new form, where every chapter has been critically revised and added to, the illustrations improved, and the recent work included, it should be assured of a new lease of life.

C. H. O'D.

Geologie Südamerikas

Von Prof. Dr. H. Gerth. (Geologie der Erde, herausgegeben von Prof. Dr. Erich Krenkel.) Teil 2. Pp. vi+201–389+plates 18–30. (Berlin: Gebrüder Borntraeger, 1935.) 19.60 gold marks.

THE second part of Prof. Gerth's exceedingly useful treatise on the geology of South America deals with the geological history of the continent during Mesozoic times and summarizes, in a very concise manner, the rather scattered literature on the subject.

The method of treatment is similar to that employed so successfully by the author in vol. 1, and the regional discussion of each system or formation is followed by a short section dealing with the main events throughout the continent as a whole.

In contrast to the northern hemisphere, the Mesozoic era in the southern continent was a period of intense and widespread igneous activity which reached its maximum expression during the Trias but recurred locally during the Jurassic and Cretaceous. The author brings this igneous activity into line with the tectonic status of the continent and traces the development of the three great, independent zones of sedimentation from which the Tertiary orogenic zone developed.

The numerous correlation tables and abundant references to literature considerably increase the value of this excellent book, which must prove of interest and value to all geologists, and not merely to those directly concerned with the problems of South American geology.

Beiträge zur Herkunftsbestimmung bei Honig

Band 1: Pollengestaltung und Herkunftsbestimmung bei Blütenhonig; mit besonderer Berücksichtigung des Deutschen Trachtgebietes. Von Prof. Dr. Enoch Zander. Pp. 343+80 plates. (Berlin: Verlag der Reichsfachgruppe Imker E.V., 1935.) 18 gold marks.

HONEY contains large numbers of pollen grains of the blossoms visited by bees, and, consequently, a study of the pollen may yield considerable information as to the source of a honey sample—not only the flower-source, but perhaps also of the district or country of origin.

This volume contains an exhaustive account of the pollen forms that have been noted in German honey and also in occasional samples from other lands. Since the German and British floras have much in common, British students may find this work useful. Descriptions of the pollen of nearly six hundred species of plants belonging to 109 families are supplied, and pollen characters such as size, shape, number of pores and furrows are also marshalled in lists. Photographic illustrations of the pollen of nearly 350 species are also included in double-sided plates. These plates are disappointing. Each pollen form is generally shown twice, at magnifications of 160 and 450 times. For all but a small number of the larger pollen grains, the lower magnification is too low to give a picture of any value in a work of this kind, while even at the higher magnification details of diagnostic value are often obscure.

Deterioration of Structures in Sea Water

NOT the least important of the matters which concern the civil engineer engaged on port and maritime works, such as docks, jetties, wharves and piers, is the durability in a marine environment of the materials available for constructional purposes. Timber, iron and steel and concrete immersed in sea water are exposed to the action of agencies producing damage and deterioration to a far higher degree than those characteristic of a purely atmospheric environment. Timber is not only particularly prone to 'rot' or decay at or about the water-line, especially if that fluctuates in level, but also it is assailed by marine organisms of highly destructive capability, while the chemical action of the salts in sea water is equally potent, under suitable conditions, in causing and fostering corrosion in metals and disintegration in concrete. When, therefore, the Institution of Civil Engineers, in 1920, instituted a Committee of Inquiry into the Deterioration of Structures in Sea Water, it took a step which had long been desirable and which, it may confidently be asserted, has been of inestimable advantage both to the profession and to the public at large. An investigation of the kind in question is bound to be prolonged, since certain deleterious processes are slow in action, though their cumulative effect over a number of years may be extremely serious and even fatal. Each year, the Committee has published the results of its inquiries in the form of interim reports, and now it is felt that the time has come when it is fitting to issue a connected account of the whole of the investigations which have been carried out up to date, and the conclusions which, in the opinion of the Committee, may reasonably be drawn from the results so far obtained.

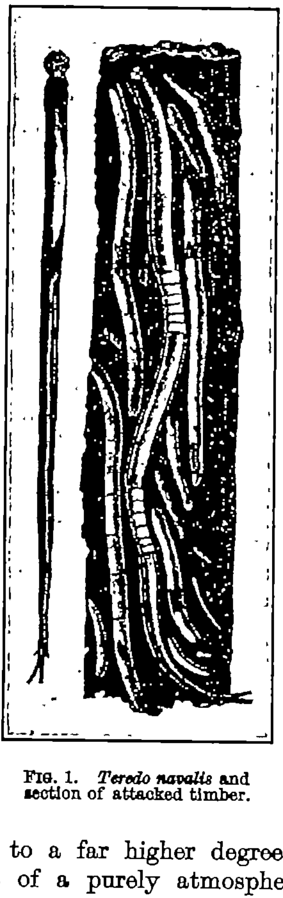

FIG. 1. *Teredo navalis* and section of attacked timber.

This has been done in a volume which has been published by the Department of Scientific and Industrial Research* embodying the fifteenth report of the Institution Committee, though the Department is careful to state that it is not responsible for the statements made or the opinions expressed therein. A similar disclaimer is made by the Institution as regards endorsing the views of contributors whose names appear in connexion with their work.

The Report comprises four sections, relating respectively to the preservation of timber, the corrosion of steel and iron, the protection of steel and iron by means of paints and other preservatives, and lastly, the deterioration of reinforced concrete.

Omitting decay, the principal cause of damage to timber structures in sea water is the *Teredo* or *Bankia*, commonly known as the ship-worm, and certain allied species (Fig. 1). The ravages of these molluscs were evident in the earliest days of shipbuilding, and they are recorded to have proved disastrous in the fourth voyage of Columbus, whose ships were "pierced with worm-holes like a bee-hive". At the present day, the damage done to timber piling in various parts of the world may be reckoned in millions of pounds. The Romans are stated to have made the discovery of a species of wood which is immune, but their secret is lost, and so far as current knowledge goes, there is no timber which is indubitably free from liability to be attacked. As the result of the experiments carried out, the Committee came to the conclusion that "no process for the preservation of timber was more satisfactory than that of impregnation with creosote" and that "the efficacy of the process depended on the completeness with which the penetration of the creosote into the timber had been effected".

---

* Department of Scientific and Industrial Research. Deterioration of Structures of Timber, Metal and Concrete exposed to the Action of Sea-Water. Fifteenth Report of the Committee of the Institution of Civil Engineers: being a General Description of the Experimental Work carried out by the Committee to date. Edited by S. M. Dixon and H. J. Grose. Pp. xvi+188+80 plates. (London: H.M. Stationery Office, 1935.) 12*s*. 6*d*. net.

In order to increase the degree of penetration, incision of the fibres was resorted to, and the results of the operation are stated to have been satisfactory, the depth of the penetration being governed by the depths of the incisions, which had to be limited "in some cases" because there was a danger of injuring the timbers if the depth of the incisions exceeded ¾ inch. The warning is significant, and there are those who will feel that incision is a method to be used with extreme caution, since injury to the fibres can scarcely be avoided, with consequent impairment of strength. The normal process of impregnation with hot creosote does not appear to affect the strength of timber to any material degree, though high temperatures were observed to produce some reduction of strength. The arsenical compound, chlorodihydrophenarsazine, commonly called "D.M.", proved very deadly to *Teredo* when in the state of free swimming larvæ. The experiments did not definitely show creosote to be an efficient protection in the case of crustaceans, such as *Limnoria*, though it appeared to have some useful effect against *Chelura*. Prof. G. Barger contributes a detailed account of his experiments with various toxins, and Prof. S. M. Dixon describes his mechanical tests of foreign timbers, untreated and creosoted, with a note on incising.

The corrosion of metals constitutes a wide field of inquiry in itself, and though in the present instance limited to iron and steel, specimen bars of no less than fourteen different materials were selected for experiment: these included three representative rolled irons, four ordinary steels, two types of cast iron and five special steels. In their choice of specimens, the Committee had the advice of Sir Robert Hadfield, and the examination of the bars after exposure was made by Dr. J. Newton Friend. The test specimens were in general 24 in. long by 3 in. by ½ in.

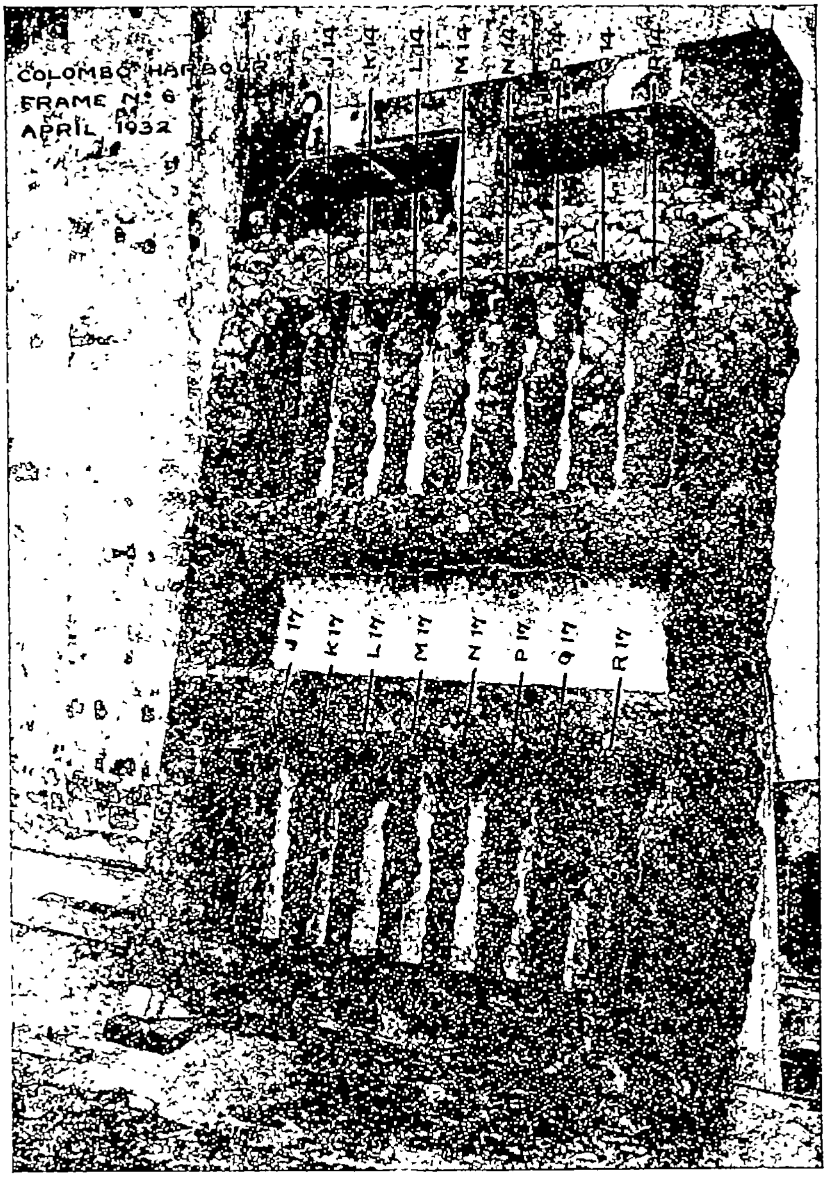

FIG. 2. Frame containing bars exposed to half-tide conditions (upper part) and to complete immersion in sea water (lower part) at Colombo for 10 years. Reproduced by permission of the Controller of H.M. Stationery Office from "Deterioration of Structures in Sea Water". Crown copyright reserved.

On the whole, there was found to be little to choose between the wrought irons and the ordinary carbon steels used in the research, as regards their mean resistance to the various types of corrosion studied; and increasing the carbon content of ordinary steel from about 0·24 to 0·40 per cent did not appear appreciably to affect the resistance of the metal against corrosion. The addition of 0·6 and 2·2 per cent of copper to mild carbon steel markedly increased the resistance of the metal to aerial and freshwater corrosion, but this advantage did not appear to be maintained in the half-tide and complete immersion tests in sea water. The addition of chromium proved beneficial in the tests above high-water mark, but in the half-tide and complete immersion tests it resulted in excessive pitting. The best results were obtained by adding a proportion of nickel to the steel, an addition of 36·6 per cent rendering the material exceptionally resistant under all conditions. The cast irons resisted aerial corrosion exceedingly well and fresh-water reasonably well, but in the half-tide and complete immersion tests in sea water, corrosion frequently penetrated to the middle of the bars through pores and casting flaws. It is to be noted that the corrosion of the test bars was complicated by the occurrence of marine growths, including barnacles and oysters (Fig. 2).

The preservative effect of paints and other coatings on a number of mild steel plates (2 ft. long by 6 in. wide by about 0·1 in. thick) was studied, and the tests under the supervision of Dr. Newton Friend yielded results of much interest. The advantage of removing the mill-scale prior to coating, either by pickling or sand-blasting, was brought out clearly. Immersion in sea water and subsequent scraping was not so satisfactory. The plates were treated with red iron oxide paint (adopted as the standard for comparison) and with ordinary red lead paint with various Pb_3O_4 contents. The red lead paints showed distinct superiority in the aerial and half-tide experiments, but not in the total immersion tests. A series of plates were galvanized and a further set covered with tar and bituminous mixtures. Galvanizing proved very successful with a coating of about 20 oz. of zinc per square yard. Coal tar gave excellent results and proved in all circumstances much better than iron oxide and lead paints. Bituminous solution gave poor results in aerial tests, but excellent results in the half-tide and complete immersion tests.

The experimental investigation of the durability of reinforced concrete in sea water has been conducted by Dr. R. E. Stradling. The experiments have involved the preparation of 474 reinforced concrete piles and 5,388 cylinders of different composition and treatment. The longest period of exposure experienced by any of these series as yet is only 5½ years, and it is therefore premature to draw other than merely tentative conclusions therefrom. As further examination may lead to modified views, it is scarcely advisable at this stage to do more than record the continuance of the exposure tests under various conditions at stations at Sheerness, Watford and the Gold Coast.

The volume, which is well illustrated and accompanied by diagrams and tables of great interest, will be of value to all who are in any way responsible for the maintenance of structures in a marine environment. It should be added that the research is now being carried on by means of the financial assistance received from a large number of dock and harbour authorities. There is a good index.

In connexion with the foregoing review, it is appropriate to notice a paper on "The Corrosion of Iron and Steel" by Sir Robert Hadfield and Mr. S. A. Main which was read at a meeting of the Institution of Civil Engineers on April 7. The paper was essentially an extension and amplification of the Committee's Report, in that it surveyed more completely the field of investigational activities in regard to the corrosion of ferrous metals since 1922, the date of a previous paper on the subject by Sir Robert Hadfield. Emphasis was laid on the importance of the study of corrosion from the testimony of Dr. F. N. Speller, director of research at the National Tube Company, Pittsburgh, U.S.A., who had made a careful estimate of the total amount of steel in use in the world and found it to be about 1,200 million tons, of which 700 million tons is probably in use in the United States. Dr. Speller further estimated that about 75 per cent of the steel requires protection in order to be used.

Alluding to the work of the Committee, it was stated that altogether 1,350 specimens of carbon and special steels were prepared by Messrs. Hadfields of Sheffield for experimental purposes, and that in regard to exposure to air, the order of increasing severity for general wastage at the stations selected for observation was invariably Halifax (Nova Scotia), Auckland, Plymouth and Colombo. Climatic temperature, which is highest at Colombo and lowest at Halifax, evidently must have a definite influence in promoting aerial corrosion. This factor, however, did not operate to the same extent under half-tide conditions or for total immersion: presumably, therefore, the local character of the sea water may be of more importance than its temperature. The evidence of the behaviour of iron and steel under half-tide conditions is especially instructive, being contrary to the widely accepted idea that exposure "between wind and water" is particularly favourable to corrosion. In the great majority of cases among ordinary steels and rolled irons, the wastage at half-tide is intermediate between that experienced under aerial and total immersion conditions.

The authors gave some examples of the severity of the corrosion experienced in the Gulf of Paria, where the United British Oilfields of Trinidad, Ltd., reported that a 5/16 in. mild steel plate, forming the bottom of a storage tank, was eaten through in nine months. Among the protective measures discussed, special mention was made of oxide films, not more than 1·6 millionths of an inch in thickness, yet capable of providing an armour, or first line of defence against corrosion. In most cases of general wastage of steel, the removal of the rolling-mill scale, prior to exposure, had the effect of increasing the amount of corrosion, but, on the other hand, as regards pitting, its influence was almost entirely favourable. The wastage of cast iron was generally very much less than that of the rolled irons and steels, and the pitting in a five-year test was negligible.

BRYSSON CUNNINGHAM.

Insect Life of Temporary Rain Swamps in British Guiana

By F. A. Squire, Department of Agriculture, British Guiana

TWICE a year, during the months immediately preceding and following the solstices, the low-lying, badly drained grasslands of the coastal belt of British Guiana are converted into temporary swamps by the heavy rains which fall during those periods. This condition naturally varies a good deal in extent and duration, but generally lasts for at least several weeks. In that time the swamps become the home of innumerable insects of diverse species, some of them of the greatest concern to mankind, and all of them very interesting.

The following account is based on observations made during the mid-year rainy season of 1935. The rains commenced on May 16 and continued with daily precipitations and frequent heavy downpours up to the end of June, when dry spells began to intervene. Up to this point the season was typical, but an opportunity to prolong the investigation was afforded by an unusually wet July and August. The rainfall recorded at the Botanic Gardens, Georgetown, for the months in question was: May, 11·56 in., June, 14·37 in., July, 8·12 in. and August, 13·78 in., totalling 47·83 in. With the cessation of the rains, the swamps drain off and vanish almost as suddenly as they appear, so that there is never any stagnation.

Bearing in mind the abruptness of the onset of the rains, it is perhaps scarcely necessary to labour the point that when these aquatic conditions arise, there is a complete and somewhat sudden change in the savannah population—the dry season dwellers evacuating their territory with a good deal of haste and panic, and often with considerable loss of life. This is quite commonly observed in the case of *Solenopsis*, the red stinging ant. This notorious insect infests, and often monopolizes, the countryside—especially low-lying grasslands. Here it establishes its colonies in ever-increasing numbers, and it would, in a short time, surely become a terrible scourge but for the blessed ruthlessness of Nature. With the advent of the rains and the flooding of the savannahs, these colonies are promptly inundated. How the ant meets this parlous situation by forming living rafts for the purpose of salvaging the brood and fertile queens is well known. But how many of these castaways ever reach safety, and what is the extent of the subterranean mortality ?

Even more disastrous is the effect of the floods on other underground insects, especially the larvæ and pupæ of humous and root-feeding Coleoptera. These frequently have no aquatic adaptations, and are consequently easily overcome by excessive moisture. These inhabitants of the soil have, presumably through natural selection, come to pass their more defenceless stages during the dry seasons. But this arrangement is precarious, for the weather is often capricious, and unseasonable deluges not infrequently occur, creating very unfavourable conditions for the soil fauna. The Dynastids, *Dyscinetus geminatus* and *D. bidentatus*, in particular, are very adversely affected, and may be prevented from making their appearance in pestilential numbers for several years by such an occurrence. Tangible evidence of the havoc caused is not lacking, for the receding waters leave behind them innumerable dead grubs scattered over the countryside.

Above the ground another story is told. The rather populous Orthoptera and Hemiptera that may, in dry weather, be swept up from any patch of grass, are better equipped for flight to higher levels ; yet many are trapped, and may be seen clinging to a hopeful blade of grass or making sorry efforts to swim with ill-adapted limbs. There is, indeed, one local grasshopper which, I believe, must be unique, whose life is normally passed in semi-aquatic surroundings and whose hind-tibiæ are curiously suited to this element, being flattened and expanded to form paddles.

The disappearance of the dry season population with the advent of the rains is soon followed by the appearance of a number of bizarre water dwellers, the life of which, for the few weeks of the duration of the swamps, is a fierce internecine war. Among the first to colonize this new environment are the mosquitoes. The females continue to oviposit throughout the season, thus keeping the swamps well supplied with larvæ and pupæ of all ages. Yet this apparently ideal breeding ground is but a death trap for the species. The vast majority never reach maturity, but fall a prey either as larvæ or as pupæ to predacious insects. By far the most numerous species is *Culex similis* Theo. Also present, though in decidedly fewer numbers, is *Urotaenia lowii* Theo. *Anopheles tarsimaculata* Goeldi is found here and there in shady spots.

Chief among the natural enemies of the Culicidæ are dragonfly larvæ, of which about six different species were found. They are the most successful of the swamp fauna. This is due to their great agility, their cryptic patterns, their curious habit of camouflaging themselves with débris when at rest, and perhaps to their repulsive, spidery appearance. That they are not far more predominant is probably due to their deplorable cannibalism. While the young nymphs content themselves with mosquitoes, the larger instars are inclined to disdain this exiguous diet and go for members of their own family, which they disembowel with the movable hooks of their mask. Their cannibalism is, however, facultative; in fact, they have a catholic palate, and their diet includes tadpoles, two species of which swarm in the temporary swamps, young grubs of water-beetles, tabanid maggots and Belostomatidæ.

It is a noteworthy fact that these Odonata pass through their life-cycle quite comfortably during the short duration of the swamps. It seems that the long life-history ascribed to them in text-books is largely a laboratory fiction, as they do very poorly in captivity, even when natural conditions are closely simulated.

Two species in particular, *Erythrodiplax umbrata* Linn. and *Leptothemis vesiculosa* Fabr. were kept under observation in an aquarium. By far their most striking peculiarity is their habit of camouflaging themselves. They kick up the sediment, which settles in a fine shower on their limbs and body, and covers them like a mantle. In this manner they not only escape the unwelcome attentions of their enemies while resting or during moulting, but are also better able to seize their prey unexpectedly, thus securing an initial advantage in combat which may be sorely needed when the object of their designs is a well-matched nymph or a robust *Hydrous* grub.

Full-grown larvæ of *Hydrous* are never attacked, as they would be rather unmanageable, and a discreet preference is shown for harmless fare like tadpoles. These make easy prey, and are simply seized under the jaw and gnawed to pieces without being able to offer any resistance beyond an ineffectual wriggle. With this defenceless pabulum the dragonflies make merry, and for our immunity from at least one of the seven plagues of Egypt we owe a good deal to the Odonata.

In their turn, however, the Odonata are beset by rapacious foes. Among these the most fearsome is the silver water-beetle *Hydrous smaragdinous*. The adult is an inoffensive vegetarian, so that it is all the more surprising to find the larvæ equipped with a pair of huge crescentic jaws. Dragonfly nymphs, despite their superior agility and cryptic colouring, fall easy prey to these slug-like creatures which, covering themselves with fine mud, and moving slowly but quietly, are able to approach unobserved within striking distance of their quarry. Their favourite food is the tadpole, which is secured in an interesting manner: the tadpole, having the advantage of speed and elusiveness, is first of all rendered *hors de combat* by being deprived of its tail. In many cases this is accomplished by a single sweep of the great jaws, but where the victim is more robust, the amputation is not quite so artistic.

The life-history of the silver water-beetle is of unusual interest. The egg mass is approximately hemispherical and about ¾ in. in diameter. It consists of dry froth, with an outer impermeable crust. The flat side has a hardened, triangular pad which floats vertically with the apex up, and is invariably attached to a straw which serves to camouflage it. The eggs are pale yellow and about 4 mm. in length, and are placed vertically in the side of the hemisphere in a single layer of about three hundred. The rest of the space being taken up by froth, the centre of gravity is low, thus stabilizing the egg mass. More remarkable is the rapidity of the embryology: the eggs are laid within a day or two of mating and are quite undeveloped at oviposition; yet within three days the larvæ emerge. The outer envelope is ruptured round the base of the triangular pad and the grubs swim out. There are three casts, the first taking place two days after eclosion, the second about four days later, and the last before pupation, seventeen days after that. By this time the grub has attained a length of two inches. There is a quiescent prepupal stage of six days, followed by a pupal instar of five days. Thus the total life-cycle occupies about thirty-one days. Another water-beetle with similar biology occurring in the temporary swamps is *Tropisternus lævis* Sturm.

Other insects of interest in this association are the Belostomatidæ, of which several species occur. Their prey consists of mosquito, dragonfly and tabanid larvæ, which they seize with their prehensile forelegs.

In conclusion, attention may once more be directed to the rapidity with which the temporary swamps are colonized, and the intense and incessant competition among the colonists and its effect on the mosquito population. The comparative paucity of mosquitoes during the thick of the rains is a common experience in British Guiana, and is generally attributed to the destruction of larvæ by excessive flooding. While there may be something in this, there is little doubt that it is due in a far greater measure to the mosquito's aquatic associates. These are slower at colonizing at the onset of the rains, and cannot establish themselves at all in the ephemeral puddles that result from the intermittent showers towards the end of the season. This suggests a reason for the prevalence of mosquitoes at the beginning and at the end of the rains, and their scarcity when the rainy season is in full swing.

Obituary

Dr. W. J. S. Lockyer

THE sudden death of Dr. Lockyer has deprived astronomical circles of a familiar and welcome figure. While walking down to his house from the Norman Lockyer Observatory on July 15 he was seen to fall on his face; and when some men close by went to help him up, he was found to be dead. About two years ago he was laid up for several months on account of phlebitis, and his death seems to have been a sequel to this attack.

To all his friends, Dr. William James Stewart Lockyer was affectionately known as 'Jim', and by all of them he will be greatly missed. He was the fifth son of Sir Norman Lockyer and was born on January 3, 1868. His mother died when he was eleven years of age, and the present Lady Lockyer was married to Sir Norman in 1903. The stages of Dr. Lockyer's education at Cheltenham College, Trinity College, Cambridge, the Royal College of Science, South Kensington, and the University of Göttingen, all led naturally to a scientific career and to his carrying on the astronomical studies of his distinguished father. The subject of the thesis for which he received his doctorate at Gottingen in 1896 was the variable star η Aquilæ, all the available observations of which he submitted to full discussion with some interesting conclusions. Among the results obtained was that the epoch of maximum luminosity oscillates to and fro to the extent of five hours on either side, with a period comprising four hundred maxima. The minima are also subject to a similar oscillation, and four secondary undulations were revealed on the curves representing the variability of the star's magnitude, recurring at intervals of forty-three hours, or one-quarter of the main period.

Variability of another kind, namely, that of the spectrum of the star γ Cassiopeiiæ, was the subject of Dr. Lockyer's most recent papers to the Royal Astronomical Society. This star has a constant magnitude of 2·25, and its spectrum was also believed to be constant until a close examination of photographs taken by Dr. Lockyer proved it to change in a very peculiar manner. The spectrum contains hydrogen lines each made up of double emission lines superimposed on a broad absorption line. The two components of each of the double emission lines undergo regular changes of relative intensity; and in his last paper on this star, contributed to the Royal Astronomical Society a little more than a year ago, evidence was presented of some very remarkable variations of this character.

This paper was one of forty dealing with spectroscopic work carried out at the Norman Lockyer Observatory, Sidmouth, since 1920, nearly all of them by Dr. Lockyer himself. The Observatory was founded by Sir Norman with the help of sympathetic friends in 1912, after the decision to transfer to Cambridge the Solar Physics Observatory in which he had carried on astrophysical and astrochemical work continuously since 1875. It was first called the Hill Observatory, but was given its present name after Sir Norman's death in 1920. Four years earlier, the Norman Lockyer Observatory had been formed into a Corporation under the Companies (Consolidation) Act, 1908, with Sir Robert Mond, who was a school friend of Dr. Lockyer's at Cheltenham College, as chairman. Dr. Lockyer succeeded his father as director of the Observatory in 1920, and though he usually had only one assistant observer, the amount of original work done has been remarkable, with the result that the Observatory now possesses as fine a collection of photographs of stellar spectra as any observatory in Great Britain. Such a record is particularly good for an institution maintained entirely by private benefactors and without any State aid.

Both in association with his father, and separately, Dr. Lockyer took part in a number of total solar eclipse expeditions. Among these were Government expeditions to observe the Vadso (Lapland) eclipse of 1896; Viziadrug (India), 1898; Alicante (Spain), 1900; Palma (Majorca), 1905; and Vavau (Tonga Islands), 1911, when he was the chief of the expedition. Other eclipses observed by him were those of 1912 (France); 1921 (Scotland); 1927 (England);

and 1932 (Canada), and whenever weather conditions were favourable he was successful in adding something to our knowledge of solar phenomena revealed during totality. His skill as a photographer, and familiarity with astronomical instruments, made him particularly valuable to every eclipse expedition of which he was a member.

While certain problems relating to the constitution of the sun can only be studied during the brief moments of total eclipse, there are many others which require for their solution the collection of observations over a long period. Among these is the relation between solar changes and terrestrial weather, to which subject Sir Norman and his son contributed some notable papers. Upon the initiative of Sir Norman, a committee for the study of such changes was appointed by the International Meteorological Committee in 1903, and Dr. Lockyer became secretary of it. Periodic plus and minus 'pulses' of rainfall in India were described by Sir Norman and Dr. Lockyer in a paper read before the Royal Society in November 1900, and were shown to be related (sometimes inversely) to similar variations at Mauritius, Cordoba (South America), the Cape of Good Hope, and other places. Attention was afterwards devoted to an examination of the variations of pressure over the Indian and other areas, and a period of 3·8 years was found in the mean variation over the whole of India and the other areas. An inverse variation was found in the pressures at Cordoba ; in fact, there was a 'see-saw'. The area affected by this barometric see-saw was extended in a later paper before the Royal Society to Java, Ceylon, Mauritius and Australia.

These studies of periodic variations in the earth's meteorological elements are closely related to solar conditions. It was shown by Dr. Lockyer that, underlying the ordinary solar cycle of eleven years, there is another of greater length, namely, thirty-five years, or about three cycles of solar activity. This corresponds to Brückner's well-known climatic cycle of about thirty-five years, and thus associates weather changes on the earth with periodic variations of solar phenomena. What exactly is the relationship between the two sets of changes has yet to be determined, and the criterion of correlation coefficients has taken the place of that of curve parallels, but Dr. Lockyer's studies of the problem are still important contributions towards its solution.

Dr. Lockyer was keenly interested in aeronautics, and he made his first ascent in a balloon in 1907, with the late Hon. C. S. Rolls as pilot. For the next few years he was in the air in balloons and aeroplanes as often as his work or chance permitted, invariably accompanied by his camera and frequently with other scientific instruments, such as experimental direction finders and similar gadgets. During the Great War he was commissioned in July 1915 as a lieutenant in the Royal Naval Volunteer Reserve, attached to the Royal Naval Air Service, and two years later was promoted to the rank of lieutenant-commander. He served as commanding officer at several anti-Zeppelin stations and also in other capacities, such as intelligence officer to H.Q. Manston and Westgate R.N.A.S., ground instructor Netheravon (Wilts), and meteorological officer at Burnham Newton (Norfolk) and Orfordness (Suffolk). He became full major in the Royal Air Force in 1918 and was demobilized in August 1919, when he again took up his astronomical work.

Dr. Lockyer served on the Council of the Royal Astronomical Society from 1927 until 1929, and again from 1931 until the present year ; he was also a vice-president of the Society in the period 1933-35. He was honorary lecturer in astronomy at University College, Exeter, but most of his active life was devoted to observational work at South Kensington and later in the Observatory founded by his father on the top of Salcombe Hill, overlooking Sidmouth. He was married, and his widow survives him, but he leaves no children to continue or extend the work which has given the name of Lockyer a permanent place in the history of astronomical science. He will, however, not only be remembered in these records, but also by a large circle of personal friends, who will long cherish his memory with affection and esteem.

Baron Axel von Klinckowström

THE death of Baron Axel von Klinckowstrom, which occurred in the month of May at his home, the family estate of Stafsund on the island of Ekerö near Stockholm, removes one of the few remaining links with Nordenskiold, the explorer. Klinckowstrom, who was born in 1867, accompanied Nordenskiöld to Spitsbergen in 1890 as a young zoologist, and in 1891 himself undertook a zoological expedition to Surinam. After his return, he devoted himself to biological research first at Stockholm and later at Wurzburg under Sachs and Boveri. During these years he published a number of contributions to embryology, anatomy, variation and inheritance.

In 1895 Klinckowstrom was appointed University lecturer at Stockholm, and later undertook a number of expeditions to the Arctic and Antarctic. On his return he enriched the museums of Sweden by the presentation of his valuable collections. In his later years he devoted himself to bacteriological research carried out in his private laboratory at Stafsund. His many-sided interests embraced poetry and the history of art, and he was well known in Sweden as a writer of books of travel and adventure. His many friends will cherish the memory of a charming personality.

E. KLIENEBERGER.

WE regret to announce the following deaths :

Dr. Charles E. Johnson, director of the Roosevelt Wild Life Station at the New York State College of Forestry, on June 6, aged fifty-six years.

Prof. A. P. Karpinsky, president of the Academy of Sciences of the U.S.S.R., well known for his work in geology and palæontology, on July 14, aged eighty-nine years.

Prof. J. H. Muller, professor of chemistry of the University of Pennsylvania, an authority on the chemistry of germanium, on June 18, aged fifty-three years.

News and Views

The Medical Profession and Chemical Warfare

WE are glad that the British Medical Association, during the session held at Oxford on July 17–25, gave consideration, at the annual representative assembly on July 17, to the subject of chemical warfare. The Council of the Association reported that the question of the protection of the community against the effects of poison gas is being examined in connexion with the Air Raid Precautions Department of the Home Office before any definite proposals are made. After discussion of a resolution submitted by the North Glamorgan and Brecon Division of the Association, the following amendment was adopted: "That this meeting condemns unreservedly the use of poison gas in warfare as inhuman in its results and degrading to civilization, and relies upon the council to do everything in its power with a view to securing the co-operation of the medical profession in all countries in order to prohibit the use of poison gas." In the course of the discussion, an appeal was made to men of science generally, as well as to members of the medical profession, to protest collectively against the destruction of civilian populations through the use of poison gas, and to try to secure international co-operation with this end in view. Even though politicians may consider it impracticable to do anything to prohibit the destruction of human life by indiscriminate chemical warfare, yet scientific workers should let the community know that they dissociate themselves from the use of such methods. We hope therefore, that at the forthcoming meeting of the British Association at Blackpool the lead given by the British Medical Association will be followed; so that science may not be understood by silence as acquiescing in the application of its discoveries to the degradation of civilized life.

Native Territories and the Union of South Africa

QUESTIONS in the House of Commons on July 16 indicated that no little consternation had been aroused in certain quarters by Mr. Pirow's statements on his return to South Africa as to the trend of opinion in Great Britain on the question of the future of African mandated territories. To some extent, this was allayed by the Prime Minister's assurance that Mr. Pirow's opinions are personal and that in any event, the question falling outside the scope of his mission, his view has no basis in official discussion. The House further elicited from the Under-Secretary of State for the Colonies an explanation of a somewhat cryptic statement by General Hertzog in the Union Parliament in making provision for an expenditure of £35,000 for "development and improvement in native territories", which has been taken, not unjustifiably, as pointing to the transfer of the native territories of Bechuanaland, Basutoland and Swaziland to the Union Government at no distant date, although the precedent condition of native consent, to which the British Government is pledged, is not yet fulfilled. Mr. MacDonald's reply clarified the situation. General Hertzog, it would appear, was defending an offer of the Union Government to contribute towards certain development schemes as a step towards the co-operation with the native authorities which has been agreed upon as a desirable policy. On July 15, Mr. MacDonald stated in a written reply that the offer of the Union Government is directed to three objects: (1) anti-soil erosion work in Basutoland, (2) provision of water supplies in Bechuanaland, and (3) conservation of water in Swaziland. Notwithstanding assurances that acceptance of the offer would not impair the pledges of His Majesty's Government in the United Kingdom, the uneasiness of the native authorities in the Protectorates is such that this offer is now in abeyance; but Mr. MacDonald stated that the question of assistance out of United Kingdom funds is under consideration by the Colonial Funds Development Committee.

World Fellowship

A GENERAL meeting at Caxton Hall, Westminster, on July 18, concluded the proceedings of the World Congress of Faiths, which had been in session in London since July 3. On a broad view of the numerous contributions to discussion of world fellowship made by the delegates from the various faiths, it is evident that there is in each a body of opinion which is prepared to build upon the foundation of a common ethical element in an effort to co-operate in the solution of problems of a wider general application in present-day conditions. A spirit of good will and general agreement was perhaps more marked than any movement towards specific application at the moment; but it is, in any event, a distinct gain that an opportunity has been afforded a mixed assemblage to appreciate at first hand the distinctive outlook on, and approach to, the problems of the organization of life under different creeds and in various environments. Neither pious enthusiasm, however, nor even profound conviction, such as usually finds expression on these occasions, necessarily leads to tangible results; and to keep alive and give effect to the spirit of which the Congress has been a manifestation demands some channel through which it may be directed in order to avoid waste of energy. This aspect, happily, has not been overlooked in the present instance; and, at the last general meeting, the delegates decided to institute machinery to continue the work of spreading world fellowship through religion. It was agreed that all who presented papers, acted as chairmen, or led discussion, should form a council, and that a continuation committee should be appointed. The members then elected included Sir Francis Younghusband, Sir Herbert Samuel, Sir Sarvepalli Radhakrishnan, Mr. H. N. Spalding and Sir Abdul Qadir, with Mr. A. Jackman as secretary.

New Heating Laboratory at the Building Research Station

A NEW laboratory for research on the heating of buildings has been completed at the Building Research Station of the Department of Scientific and Industrial Research so that work can go on all the year round, instead of only in the winter. The laboratory was opened on July 22 by Sir Frank Smith, Secretary of the Department of Scientific and Industrial Research, on the occasion of the annual visit to the Building Research Station of the Institution of Heating and Ventilating Engineers, which is providing a sum of £1,500 to enable the studies, at the Station, of heating problems to be speeded up and extended. The laboratory is one room within a larger room. The smaller room, which is 18 ft. × 12 ft., is the test-room which is to be heated in all the different possible ways. It has a ceiling which can be screwed up or down so that both low rooms and high rooms can be studied. The larger room in which the test-room is situated isolates it completely from outside weather effects. The various walls of this outer enclosure can each be refrigerated and their temperatures can be controlled to 0·1° F. Modern heating methods have been utilized in the control of the outer enclosure. Every surface is panel-heated or panel-cooled by brine which circulates in pipes in the walls, floor and ceiling. For cooling the brine which refrigerates the walls, a $4\frac{1}{2}$-ton ammonia compressor is installed in the engine-room at one end of the laboratory. At the other end of the laboratory is an instrument room, where records are made of the conditions in the test-room and its enclosure. The new laboratory provides unique facilities for research and will undoubtedly mean a great speeding up of heating research.

Research and Finance

IN the leading article in NATURE of July 11, there were, we regret to say, two inaccuracies which should be corrected. The system of grants in aid of the research associations and styled "the datum line system", described on p. 52, was superseded, some two years ago, by another system which, for the sake of brevity, may be called "the block grant system". The Department of Scientific and Industrial Research now makes an annual block grant to an association, provided that a definite sum is assured, in the form of subscriptions, by the industry concerned. The block grant and the industrial income have no rigid mathematical relationship ; the ruling principle being that, added together, they must provide such a sum as will, in the opinion of the Advisory Council of the Department, form an adequate financial nucleus for a co-operative research organization for the industry in question. In order to encourage further expansion, the Department offers £ for £ on sums subscribed over and above the initial industrial income, up to a stated maximum, which, again, is fixed on the advice of the Advisory Council. This new system was the outcome of the big appeal made to industry a few years ago to play its part in expanding the operations of the research associations. The other inaccuracy was the parenthetical statement, on p. 52, that the woollen industry raises its contributions to co-operative research by means of a statutory levy. It is a fact that for some years now the woollen industry has been conducting propaganda in favour of the institution of such a statutory compulsory levy, but no measure for the attainment of this object has yet been introduced into Parliament. On the other hand, it may be remembered that a Rubber Industry Bill, having for its object the institution of a statutory levy, was introduced into Parliament and finally dropped owing to the defection of a prominent firm in the industry.

Chamberlain Memorial at the University of Birmingham

IN connexion with the centenary celebrations of the birth of Joseph Chamberlain, the first Chancellor of the University of Birmingham, Sir William Waters Butler has given £10,000 to provide scholarships, to be known as the Joseph Chamberlain Memorial scholarships. The University has also received a generous benefaction from Sir Charles Hyde, Bart., who has offered £10,000 towards the museum of the new Medical School, with the suggestion that this part of the new building should be known as the Chamberlain Memorial Museum. It is felt that this gift, like that of Sir William Butler, is very appropriate to the occasion ; for it is well known that the University, of which Mr. Chamberlain was the founder and first Chancellor, occupied a foremost place in his regard, as being an essential part of the city for which he had done so much. His foresight in placing the new buildings in Edgbaston, where there would be ample room for expansion, has been notably justified in the event. It may well be that the most enduring monument to his name will be the University of Birmingham. Mr. Chamberlain's interest in medical research was made evident in the part he took in the establishment of the London and Liverpool Schools of Tropical Medicine.

Roman Sites and the National Trust

A NEW museum of Roman antiquities from Hadrian's Wall at Housesteads Camp, north-west of Hexham, was opened on July 23 by Prof. G. M. Trevelyan, vice-chairman of the National Trust. The cost of the building has been defrayed out of funds which have accumulated as a result of the greatly increased number of visitors, who now go to inspect the camp. In 1935 they numbered no less than 15,000. Housesteads, or Borcovicus, which on its north side abuts on the Wall, covers an area of five acres. It is not only one of the finest sites on the wall, but it is also one of the most completely excavated Roman camps open to view in Great Britain. During the excavations, a number of important finds were made, and these, with other antiquities, will be housed in the new museum. The site of five acres, a milecastle and three quarters of a mile of the wall itself were presented to the National Trust in 1930 by the owner, Mr. J. H. Clayton, a well-known Northumbrian antiquary. The site is now under the management of a committee, the members of which include Prof. G. M. Trevelyan and Mr. J. A. Richmond, who for some years has been one of the most active of excavators on Roman sites in Britain. In this connexion may be mentioned another addition to the Roman sites held by the National Trust. Segontium, a Roman fort in Caernarvonshire, has been bequeathed to that body by Mr. John Roberts of London, a native of Caernarvon. The antiquities, pottery, coins and implements, which were found when the fort was excavated by Dr. R. E. Mortimer Wheeler in co-operation with the Office of Works, are housed in a museum which is bequeathed with the site.

The National Trust

THE forty-first Annual Report of the National Trust for Places of Historic Interest or Natural Beauty for the year ending June 30, 1936, again chronicles a record increase in its work. Two years ago the Council reported a record addition to the properties of the Trust, and although the properties added to the holding this year are less spectacular in acreage, they are more numerous. In the two years taken together, the acreage owned or protected by the Trust has increased by nearly fifty per cent. While it may be concluded that this expansion in the operations of the Trust is an indication of an increase in public interest in the preservation of the natural beauty and historic interest of England, it is unfortunately also a gauge of the rapidity with which the threat of modern development is advancing over the countryside. Although it is true that many properties come to the Trust as the result of private benefaction by far-sighted owners, those which are acquired as the result of public appeal almost invariably are face to face with a threat of early destruction. As the Trust is able under its constitution to acquire and hold properties which are still in occupation, a sphere from which the Office of Works is barred by statute in the exercise of its function in protecting ancient monuments, the work of the National Trust is a very necessary supplement to official action, while the Trust itself is the most important, and in some cases the only, organization through which a national appeal can be launched effectively. It is gratifying to note that the Council is able to report the initiation of a scheme for the preservation of historic country houses and their contents, which adapts to English conditions the main principles of La Demeure Historique for the preservation of châteaux in France and Belgium.

The Science Museum, South Kensington

THE Report of the Advisory Council of the Science Museum for 1935 has recently been published (London: H.M. Stationery Office. 1*s.* net). For the first time, the Report is signed by Sir Henry Lyons, who succeeded the late Sir Richard Glazebrook as chairman. Sir Richard served on the Council for twenty-three years and was chairman from 1931 until 1935, and the Report contains a tribute to the work he did for the Museum. There are to-day perhaps few Government institutions doing more within the scope of their activities, for education, scientific research and industrial progress, than the Science Museum, which has become a recognized centre for special exhibitions and scientific gatherings, and a place of popular instruction. During 1935, the total number of visitors rose to 1,327,190, the highest ever reached; 25,337 persons attended the public lectures, and 8,682 the special lectures, while in the galleries were held at various times excellent exhibitions relating to rubber, welding, noise-abatement, electro-deposition and air transport. The Report contains much evidence of the thought and work devoted to the acquisition and arrangement of the exhibits and of the logical illustration of the developments of physical science in all its branches. A special feature of the Report for 1935 is a detailed review of the collections in Division V, which include objects relating to physical phenomena, the structure of matter, magnetic, electrical, thermal and acoustical instruments, and the many branches of geophysics. Once again, the Council emphasizes the need for more accommodation, and the reconstruction of the central block. The present buildings in this portion of the Museum were built so long ago as 1862, and then only formed part of the temporary buildings for the Exhibition of that year. They are quite out of date, and their replacement is a matter of urgency if the Museum is to continue to make progress as it has done in the past.

A New Fruit Juice Factory

FOR the past four years, intensive research work has been carried out at the University of Bristol Agricultural and Horticultural Research Station at Long Ashton into the possibility of utilizing surplus fruits from the various varieties of soft fruit grown in Great Britain by means of their conversion into liquid fruit products. The research work, which has been under the direction of Mr. V. L. S. Charley, B.Sc., has resulted in the production of a series of attractive products. H. W. Carter and Co., Ltd., of The Old Refinery, Bristol, 2, and 52 Queen Victoria Street, London, have now equipped the first factory of its kind in the country at North Street, Bedminster, Bristol, 3, to prepare these fruit syrups from English fruits, and a representative gathering met on July 15 to view the factory. The retention of the fresh flavour of English soft fruits when processed into a liquid form has been shown at Long Ashton to be largely a question of the amount of sugar which is incorporated with the juice. Fruit syrups with 65 per cent of sugar have been shown to be stable and to retain to a remarkable degree the true flavour of the fresh fruit. Such syrups, however, are not of general utility on account of their excessive sweetness, but if the sugar content is reduced to any appreciable extent, grave risks of fermentation and mould growth are incurred. However, it has been shown that pasteurization at 160° F. for half an hour, a treatment which is essential to obtain stability, does seriously affect the attractiveness of the finished product.

A PROCESS has therefore been evolved in which the fresh fruit juice is incorporated with sugar until

50–55° Brix is registered, and this unstable syrup is then preserved with 200–300 parts per million of sulphur dioxide in the form of potassium metabisulphite. The present syrups are intended for use primarily with milk, and it is necessary to avoid an excessively sweet product as this detracts not only from the milk flavour, but also tends to mask the fresh flavour of the fruit. The question of curdling is not serious until any addition of acid is carried out. Even with the highly acid juices of the loganberry and blackcurrant there is very little fear of curdling when the normal concentrations, which are generally acepted in the milk bars, are used. A further process of interest is the adaptation of the carefully controlled fermentation in the fruit. This fermentation is effective first in completely disintegrating the cells which thus yield a richer, sweeter juice and, secondly, in decomposing a certain amount of pectin which would otherwise be deposited in the filtered product. Remarkable results have recently been obtained by the use of pectin-decomposing enzymes in which an addition of 0·2 per cent of enzyme has reduced the calcium pectate content of the juice from 0·134 per cent to a mere trace.

The Kauri

A SMALL pamphlet, Leaflet No. 26, on "The Properties and Uses of Kauri", *Agathis australis*, by A. R. Entrican, has been issued (Government Printer, Wellington, N.Z., 1935). This timber is one of the most useful of the coniferous softwoods, and has been known in international trade for more than a century. The kauri is the monarch of the New Zealand forests, dwarfing all other species. The bole in mature trees has singularly little taper; thus, although it does not attain the height of the North American redwoods (*Sequoia*) and the Australian eucalypts, it ranks among the largest timber-producing species in the world. It is said that in yielding flawless timber of exceptionally large size, the tree is unsurpassed by any other known species. The extensive virgin forests of the early European occupation have been severely depleted, but it is of good hope for the future to hear that the remaining stands are being placed under a system of forest regulations whereby a sustained yield of this valuable softwood will be assured. Owing to its evenness of texture and ease of working, to its small shrinkage powers, medium density and excellent strength properties and high durability, the timber is able to meet the most exacting requirements. It is made use of in all classes of building and general construction, in shipbuilding, car and wagon construction, tank and vat manufacture, military bridging, and the production of dairy and agricultural machinery and so forth. It is not surprising, as has been the case with fine species in other countries, that the brunt of the fellings for ordinary utilization by the increasing population of the country fell upon this beautiful tree.

The National Institute of Agricultural Botany

AT the annual general meeting of fellows of the National Institute of Agricultural Botany at Cambridge on July 16, the chairman of the Council, Sir Daniel Hall, in the course of his address, stated that one of the primary objects of the Institute is to serve as a medium for introducing new varieties of farm crops to the public. For this purpose its trials are organized so as to provide an accurate measure of the relative merits or de-merits of each variety tested. These trials extend over three years or more, in order to level out weather differences, and are carried out at six different centres in order to eliminate differences due to soil variations. The improvements already effected in the yield of cereals make it unlikely that any new variety will show a 20 per cent improvement upon the existing varieties. Improvements in the nature of 5–10 per cent are more probable, but even a 5 per cent improvement would make a considerable financial difference to farmers. Farming is never at a standstill, and the Institute meets the changing agricultural situation by extending the scope of its trials. Trials of picking peas and chicory are now being carried out, and it is hoped that useful information will be derived from them. The potato trials at Ormskirk have done much to check the spread of wart disease by the encouragement given to the introduction of new immune varieties. Sir Daniel went on to say that close co-operation with the seed trade would be beneficial to both bodies. In serving the farmers, the Institute also serves the best interests of the seed trade, which has the highest degree of confidence in the Official Seed Testing Station. This is testified by the fact that the number of samples tested by the Official Seed Testing Station is steadily increasing year by year, and nearly 30,000 samples have been tested in the current year. In conclusion Sir Daniel expressed concern at the shrinkage in the number of fellows of the Institute: he hopes the Institute will never become a purely bureaucratic body, reponsible only to the Government.

Prevention of Tuberculosis

SIR KINGSLEY WOOD, the Minister of Health, inaugurated the twenty-second annual conference of the National Association for the Prevention of Tuberculosis at the County Hall, London, on July 16. He stated that great progress has been made in the fight against tuberculosis. For the first time on record, the total number of deaths in England and Wales from all forms of tuberculosis fell in 1935 below 30,000. The standardized death-rate from tuberculosis has fallen from 1,915 to 687 per million in less than forty years. This striking record of progress is due in the first place to remarkable improvements in methods of treatment. Much also is due to the example given by the establishment, as a result of greater knowledge and active propaganda, of voluntary sanatoria and dispensaries. It is significant that no sanatorium in the modern sense existed in Great Britain before 1898. Improved standards of living and hygiene, better housing, better nutrition, purer milk supply and general public health measures have played and will continue to play a considerable part in the attack upon this disease. But there are many opportunities for further advance. There is a great need for encouraging those who were suffering or suspected to be suffering from tuberculosis to take advantage at the earliest possible stage of the facilities provided for diagnosis and treatment. The importance also of eliminating tuberculous cattle from the herds of Great Britain is obviously very great. Bovine tuberculosis is responsible in Great Britain for a large number of deaths, probably more than 2,500 per annum, and for a still larger amount of serious illness. Much remains to be done before we can be satisfied that the whole of our milk supply is safe.

British School of Archæology at Athens

ON October 13, the British School of Archæology at Athens will celebrate the fiftieth anniversary of its foundation by holding at the Royal Academy of Arts, Burlington House, an exhibition to illustrate the discoveries in Greece and Crete which have resulted from the work of the School, together with a special exhibit devoted to the Minoan civilizations of Greece, and the excavations of the School's honorary student, Sir Arthur Evans, at Knossos, in which the School's architects took part. This exhibit is being prepared by Sir Arthur Evans himself, with facilities kindly given him by the Keeper and Visitors of the Ashmolean Museum. It is understood that the exhibition will be inaugurated by His Royal Highness the Duke of Kent, on October 13 at 3 p.m., and will be open to the public from October 14 until November 14. In connexion with the jubilee of the School, it is proposed also to raise a special fund to enable the School to increase its staff, improve its library and accommodation, and provide for the needs of the graduate students who, in increasing numbers, are sent to Greece for advanced study by the universities.

Indian Vital Statistics for 1933

THE chief vital statistical figures for British India for 1933 are: (1) total births, 9,678,876, giving a crude birth-rate of 35·5 per mille, (2) total deaths numbered 6,096,787, giving a crude death-rate of 22·4 per mille, (3) infantile deaths numbered 1,650,973, an infantile death-rate per 1,000 births of 170·5 (Ann. Rep. of the Public Health Commissioner with the Government of India for 1933. Government of India Press, New Delhi. Rs.6 as.4 or 10*s*.). The birth-rate is more than double, the death-rate nearly double, and the infant mortality about two and a half times, the corresponding figures for England and Wales. It is remarked that, contrary to some recent statements, the population of India is increasing at an alarming rate, and by 1941 will probably reach 400 millions. The total land area of British India amounts to only 2·44 acres per head of the population, but allowing for forest, uncultivated and fallow lands, only 0·72 acre per head is under food crops—quite insufficient for even the present population. Birth-control is viewed sympathetically, but only seven hundred medical women are available to instruct Indian women about it. Cholera deaths (68,318) and plague deaths (43,000) are not nearly so high as in some years, but smallpox deaths numbered 103,000, compared with 45,000 during the previous year—a disconcerting rise.

Anti-Rabic Treatment in Southern India

THE Annual Report of the Director, Major Iyengar, of the Pasteur Institute of Southern India, Coonoor, states that during the year ended December 31, 1934, 414 persons underwent the complete, and 77 an incomplete, treatment at the Institute after bites by animals supposedly rabid. For the second time in the twenty-eight years of the Institute's existence, there were no deaths from hydrophobia among those treated. Paris fixed virus was in use in the form of Semple's carbolized five per cent sheep vaccine, and at the end of the year was in its 937 passage. The vaccine was also issued from several out-centres—12,316 courses for nearly 13,000 cases, with 26 deaths from hydrophobia. In addition, anti-rabic vaccine was issued for the prophylactic treatment of 259 animals. In spite of what the Institute is doing, 412 deaths from hydrophobia were recorded in the Madras Presidency during 1934.

Northern Lights

PROF. CARL STØRMER has directed attention to a prevalent confusion between the north magnetic pole and the point on the earth where the magnetic axis meets the surface. Thus, in the supplement to NATURE of May 16, 1936, it is stated on p. 813 that "It is the distance from the magnetic axis of the earth that counts, and that axis meets the surface of the earth at the north magnetic pole, which is in the island of Boothia in Canada"; this should read as follows: "It is the distance from the magnetic axis of the earth that counts and that axis meets the surface of the earth about midway between the north magnetic pole and the north pole". This point is near North-Western Greenland, and it might be named the north axial pole. The zone or belt of greatest auroral display has this point for centre on the earth.

The Night Sky in August

THE nights during August are still rather short to afford much opportunity for a close scrutiny of the rich fields about the galactic equator, which in the British Isles passes overhead from north-east to south-west about midnight at the beginning of the month. Even at nightfall, however, the sky is distinctive with Arcturus still fairly high towards the west: Jupiter a brilliant object in the south-west: Vega, Deneb and Altair not far from the meridian: Saturn rising with Pisces in the east, whilst Capella may be picked out towards the northern horizon. Full moon occurs on August $3^{d}\ 3^{h}\ 47^{m}$ and new moon on August $17^{d}\ 3^{h}\ 21^{m}$. The brightest star to be occulted this lunation is κ Piscium (magnitude 4·9)—the reappearance may be observed on August $6^{d}\ 1^{h}\ 59{\cdot}7^{m}$ (U.T.) at position angle 267° from the north point of the lunar disk. Other occultations of stars, ranging in magnitude from 6·3 to 6·7, may be observed on August 5, 6, 10 and 13. Between August 9 and 12 occurs the maximum of the Perseid meteor shower, the radiant of which is in Perseus at R.A. $3^{h}\ 0^{m}$ and Dec. 57° N. The meteors of this shower are yellowish in colour and move with medium velocity. The orbit of the shower is well determined and coincides with that of Tuttle's Comet of 1862. On August 4, Peltier's comet (discovered on May 15 last by Mr. L. Peltier of Delphos, Ohio) is at its nearest approach to the earth at a distance of 15¼ million miles. Its computed position on August $4^d\ 0^h$ is R.A. $21^h\ 45^m\ 10^s$: Dec. 4° 8′ S., which places it in the constellation Aquarius, but the moon being full will prevent its being easily observed; otherwise it should be faintly visible to the naked eye. The comet is then travelling south rapidly and will reach 70° S. on August 24. Nova Lacertæ, which was discovered on June $18^d\ 21\frac{1}{4}^h$, probably reached its maximum brightness of about mag. 2·2 on June 20 and is now slowly fading. Its magnitude on July 17 was 6·3 according to Steavenson, so that the nova can be seen with binoculars; its position (R.A. $22^h\ 11^m\ 5^s$: Dec. 54° 59′ 42″ N.) is about 2° south of ε Cephei. The character of the nova's spectrum suggests a more rapid progress than is normally the case through the typical evolution stages of a nova.

Announcements

IN view of the Coronation festivities next year, the dates of the Royal Society soirées have been fixed well in advance. The men's soirée will be held on Tuesday, May 4, and the ladies' soirée on Thursday, May 6; it is possible that a third soirée will be arranged, but the date is not yet fixed.

IN connexion with the Second International Congress for Microbiology being held at University College, London, on July 25–August 1, an exhibition of scientific instruments has been arranged at the College. The exhibition will be open to all scientific workers, irrespective of whether they are members of the Congress or not, on July 27–29, from 10.30 a.m. until 5 p.m.

AT the Annual Summer Conference of Advisory Plant Pathologists at the University of Leeds, Dr. Geo. H. Pethybridge, mycologist to the Ministry of Agriculture and Fisheries for the last twelve years, and previously for many years in the Department of Agriculture in Ireland, was presented with a wireless receiving set, etc., as a mark of appreciation on the occasion of his approaching retirement from official service.

THE Jones-Bateman cup of the Royal Horticultural Society, which is awarded triennially for researches in the growing of hardy fruits, figs, grapes and peaches in the open or under glass, is available for award in 1936. Candidates should submit accounts of their work by October 31 to the Royal Horticultural Society, Vincent Square, Westminster, S.W.1. The work dealt with must have been carried out by the candidate in the United Kingdom mainly during the past five years.

THE thirteenth Annual Conference of the Association of Special Libraries and Information Bureaux (ASLIB) will be held in Oxford on September 18–21. On September 18, at 8.30 p.m., the president-elect, Dr. Cyril Norwood, will deliver his address entitled "The Library in the School". On September 19, at 9.30 a.m., a symposium on "Library Instruction for University and Research Students in America" will be held. Further information can be obtained from the General Secretary, ASLIB, 31, Museum Street, London, W.C.1.

PROF. E. ABDERHALDEN, professor of physiology in the University of Halle, has been nominated an honorary member of the Society of Biological Chemists at Bangalore.

THE following have recently been elected members of the Imperial Leopold Caroline German Academy of Science at Halle: Dr. Paul Buchner, professor of zoology at Leipzig; Dr. Hermann Loescheke, professor of pathology at Greifswald; Dr. C. Gósta A. Forsell, professor of medical radiology, and Dr. S. E. Patrik Haglund, professor of orthopædics at Stockholm; Dr. Knud Faber, professor of medicine at Copenhagen; Dr. A. H. M. J. Van Rooy, professor of gynæcology and obstetrics at Amsterdam; Dr. E. Leclainche, director of the international office of epizootics in Paris; and Dr. Karl Wegelin, professor of general pathology and morbid anatomy at Bern.

THE following scientific awards have recently been made by the American Medical Association: Gold Medal to Drs. Charles B. Huggins, S. W. J. Noonan and B. H. Blockson of the University of Chicago for their work in connexion with increasing blood production in the arms and legs by means of increased temperature; Silver Medal to G. C. Supple and S. Ansbacher of the research division of the Borden Company for their method of obtaining lactoflavine from milk; Bronze Medal to Dr. Alvin L. Barach of the Presbyterian Hospital, New York, for his method of providing an artificial light air in which helium is substituted for nitrogen.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A teacher of engineering (mechanical) in the Norwich Technical College—The Principal (July 28).

A lecturer in civil engineering in Armstrong College, Newcastle-upon-Tyne—The Registrar (July 30).

A statistician for a War Department establishment—The President, Royal Engineer Board, Regent's Park Barracks, London, N.W.1 (August 5).

Chemists at the Royal Gunpowder Factory, Waltham Abbey—The Principal Clerk, Central Office, Royal Gunpowder and Small Arms Factories, Enfield Lock, Middlesex (August 7).

A senior lecturer in physiology in the University of Aberdeen—The Secretary (August 15).

A technical editor at the Technical Institute, 16 St. Mary's Parsonage, Manchester, 3—The General Secretary (September 7).

An assistant lecturer in the Department of Electrical Engineering, Mathematics and Physics (with engineering degree) in the Natal Technical College—Mr. H. W. Gray, 17 Claydon Avenue, Southsea.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 169.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Order of Affinity of Metals for Copper, Iron, Cobalt and Nickel

EACH of the metals aluminium, zinc, cadmium, tin, mercury and lead is known from X-ray and thermal data to form intermetallic compounds with copper. Some of these may be prepared also by obtaining the two metals in dilute solution or suspension (1–4 per cent) at the ordinary temperature in mercury and removing excess of the more reactive metal by oxidation and the mercury by filtration and distillation[1]. In mercury, under such conditions, there is in each system a binary compound much stabler than the others, namely, $AlCu_6$, Sn_4Cu_5, ZnCu, $CdCu_4$, Hg_3Cu. The question arises: Suppose we have two of the above metals competing for copper in the medium of mercury, do both combine with copper or does one only? Or, suppose we add one metal to the compound of another metal and copper, is there a partial reaction, or does the reaction go either completely or not at all?

The analytical difficulties of this problem are not serious, and it is possible to obtain unambiguous answers to these questions. There seems to be a definite order of the above metals with respect to their power to combine with copper. It is aluminium, tin, zinc, cadmium and mercury, lead. If copper be competed for by two of these metals, the one earlier in the list combines with it, the other remains uncombined. If a metal earlier in the list be added to a compound of copper and another of these metals, the former displaces the latter completely. If the positions are reversed, no reaction occurs. Thus, when aluminium is added to any tin, zinc, cadmium or lead compound of copper, in mercury, it combines with the copper and sets the other metal free. The resulting binary is $AlCu_6$ or, more often, the stabler ternary $Al_2Cu_3Hg_6$. From neither of these can the aluminium be displaced by any of the metals mentioned. So for the action of tin on zinc-copper compounds. Ternary and even quaternary complexes are temporarily formed[2], but in the end the zinc is wholly displaced and the tin combines with the copper. Ternaries throughout complicate the issue.

Similar experiments have been done with these metals and the metals iron, cobalt and nickel, with which each of them is also known to combine. With iron the stablest compounds formed are $AlFe_3$, $SnFe_2$, $ZnFe_7$ and $HgFe_4$ (cadmium and lead do not readily combine in mercury with transition elements). The order here is aluminium, tin, zinc, mercury, cadmium and lead. Thus, neither tin nor zinc can displace aluminium from $AlFe_3$, whereas the easiest way of preparing this compound is by adding aluminium to a tin-iron or a zinc-iron compound in mercury. With cobalt the stablest compounds formed are AlCo, $SnCo_2$, ZnCo and HgCo; with nickel the stablest compounds are AlNi, Sn_4Ni_5, ZnNi and HgNi. With both these metals the order is that obtained with iron and slightly different from that obtained with copper. The corresponding experiments with manganese and silver have still to be done. The inverse problem—How does one of the metals aluminium, tin and so on, distribute itself among the other metals of the class copper, silver, iron and so on?—is analytically very hard and has not yet been solved.

The order of metals obtained in these experiments is not, and would not be expected to be, that of the electrode-potential series, because in entering into intermetallic combination the atom does not undergo the simple process of ionization of the type $X \rightarrow X^+$. It is likely to be connected with atomic diameters and interatomic distances and forces in the crystal patterns formed.

Formation of Carbon Dendrites

PARTICLES of colloidal graphitic oxide dispersed in water have a negative charge, and under a potential gradient move relatively rapidly towards the anode[1]. Under certain conditions, however, reduction of the oxide occurs at the cathode, with the formation of long carbon dendrites. This phenomenon was shown in striking manner under the following conditions.

Graphitic oxide was prepared from finely divided Ceylon graphite by treatment with the usual sulphuric, nitric acid, potassium chlorate mixture and the product washed with water. After five washings, the colloidal, supernatant, slightly viscous, brown opalescent solution (*p*H 2·88) was decanted into an inclined glass tube provided with two platinum electrodes (see Fig. 1). On applying a potential of approximately 200 volts between the electrodes, the disordered micellar lamellæ orientated themselves so that their faces were at right angles to the path between the electrodes (cf. Thiele[1]), and immediately thin carbon dendrites commenced to grow from the cathode, and the colloid started to collect round the anode.

These effects are clearly shown in Fig. 1 (*A*), which was made one second after switching on the potential. They have become much more pronounced 25 sec.

later, as is shown in *B*. *C* is a reproduction of a photograph of another tube through which current has passed for five minutes. The region of high colloid concentration can now be seen extending from the anode to the deposited carbon. Soon after this phase, the region of high colloid concentration assumed an almost rope-like appearance, connecting anode and cathode. Dendrite growth then became extremely rapid and in a few seconds the colloidal mass was reduced to carbon. *D* shows the final phase; some of the deposited carbon has floated to the top of the tube. During the whole process the potential across the tube did not vary by more than 20 volts, nor did the current exceed more than a few milliamperes. A few small bubbles of gas were liberated at both electrodes during the experiment. *E* shows carbon dendrites which have been formed in a vertical tube.

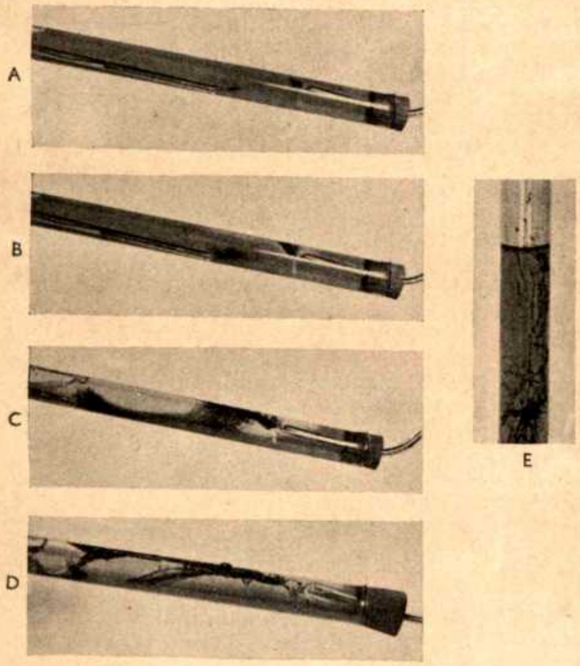

FIG. 1.

It is remarkable that in spite of the high repulsive force which the cathode must exert on the graphitic oxide particles, the latter can remain for a sufficiently long period in contact with the electrode for reduction to occur and for the resulting carbon to attach itself to the electrode. A more detailed examination of the phenomenon is being made.

A New Process of Negative Ion Formation

WHEN a stream of electrons is passed through a monatomic gas, negative ions are supposed to be formed by direct electron attachment to atoms of the gas with radiation of the excess energy. When the gas is molecular, the process generally presumed to occur is simultaneous dissociation of the molecule and attachment of the electron to one of the products of dissociation, the energy of the electron in excess of that necessary for dissociation together with the electron affinity of the atom being carried away in kinetic form by the products of dissociation.

Process	Probability × 10^4	Process	Probability × 10^4
$Hg^+ \rightarrow Hg^-$	6·4	$CO_2^+ \rightarrow CO_2^-$	2·31
$H_2^+ \rightarrow H^-$	0·104	$CO_2^+ + CO^+ \rightarrow CO^-$	10·8
$N^+ \rightarrow N^-$	1·07	$CO_2^+ \rightarrow O_2^-$	2·51
$O_2^+ \rightarrow O_2^-$	0·42	$CO_2^+ + CO^+ \rightarrow O^-$	3·37
$O_2^+ \rightarrow O^-$	1·10	$CO_2^+ + CO^+ \rightarrow C^-$	0·1

I have made an investigation of negative ion formation in mercury vapour, hydrogen, nitrogen, oxygen and carbon dioxide, and I find that the large majority, if not all, the negative ions detected are formed by a new process, and not by either of the processes mentioned above. The negative ions are formed from positive ions which extract two electrons from any negatively charged electrode, including the filament, to which they are driven. This process is energetically possible provided the sum of the ionization potential of the positive ion and the electron affinity of the negative ion that is formed is greater than twice the work function of the surface upon which the conversion takes place. The excess energy is probably dissipated by a collision of the second kind with an electron or atom of the surface.

Sometimes the positive ion is dissociated by its collision with the surface. The negative ion then formed is one of the products of dissociation. For example, the negative ions detected in carbon dioxide are CO_2^-, CO^-, O_2^-, O^- and C^-. In oxygen, both O_2^- and O^- are found. Mercury vapour, hydrogen and nitrogen gave only the atomic negative ion.

The probability of conversion of positive ions into negative ions on a nickel surface has been measured as a function of the kinetic energy of the positive ions. In each gas the probability increases as the energy of the positive ion is increased. The probability of conversion of a 180-volt positive ion into a negative ion is given in the accompanying table in units of 10^{-4}.

The negative ions come off the surface on which they are formed with a wide range of energy. From the energy distribution curves, values of the mean and the minimum accommodation coefficients for positive ions have been obtained. The energy distribution curve itself represents the probability distribution of the accommodation coefficient.

The fact that positive ions are converted into negative ions on negatively charged electrodes with the comparatively high probability shown in the above table introduces a serious, and hitherto unrecognized, source of error into many experiments, such as the recent work of Davies[1] on ionization produced by positive ions.

A complete account of this work will be published in the *Proceedings of the Royal Society*. The work on mercury vapour is already in the press, and should appear shortly.

The Form of Nuclear Levels

RECENT experimental work has proved the existence of selective absorption for neutrons the kinetic energy of which amounts to a few volts by certain nuclei[1-5]. Bohr[6] assumes that in these cases the kinetic energy of the captured neutron is equal to the difference between the energy of a level of the newly-formed nucleus and the mass defect for a neutron with zero velocity. This provides an ideal compensation method for the determination of the distance[7], breadth[5,7] and form of nuclear levels. The total energy of the level, which amounts in all these cases to some millions of volts, does not interfere with the determinations in question, since only the kinetic energy of the absorbed neutrons is measured.

When working with the cadmium filtered radiation of a source of slow neutrons, we observed big deviations from the exponential law for the absorption of resonance neutrons of rhodium (45 sec.) by rhodium and of resonance neutrons of iodine by iodine. In the accompanying table, μ means the mass absorption coefficient for the total absorption, μ' the mass absorption coefficient for each additional absorbing sheet :

	Detector Rh (45 sec.), absorber Rh					Detector I, absorber I				
Absorber gm./cm.^{2}	0·01	0·02	0·04	0·08	0·18	0·2	0·5	0·8	1·8	3·1
Absorption per cent	16	24	31	44	52	27	45	53	58	62
μ	17	14	9	7	4	1·6	1·2	1·0	0·5	0·3
μ'	17	10	5	5	1·6	1·6	0·9	0·5	0·1	0·07

Since the cross-sections of boron for radiation filtered by 0·2 gm./cm.^{2} of rhodium and detected by rhodium (45 sec.) or filtered by 3 gm./cm.^{2} of iodine and detected by iodine, were identical with the cross-sections for the unfiltered radiations, the observed deviations cannot be explained by the existence of a second level for selective neutron absorption, as in the case of silver[1,7]. We think the explanation lies in the self-reversal of the nuclear line. When both the absorption coefficient and the intensity of emission have a maximum for exactly the same energy, the middle of the line will be totally extinguished after passage through a sufficient layer of the absorber, that which penetrates consisting only of the weakly absorbable tails. By determining the absorption coefficient for each additional layer of the absorber, the whole range of values for the absorption coefficient between the middle of the line and the tails is obtained. We are thus able to determine the form of the nuclear levels. A detailed analysis and a comparison with the theoretical results of Breit and Wigner[8] will be given later. Qualitatively, the intensity distribution in the line is already obtained by plotting μ against A'/μ', A' being the fraction of the total radiation which is absorbed by each sheet. Fig. 1 shows the result for rhodium (45 sec.) plotted in this way. The real form of the line shows somewhat bigger differences of intensity. The half-value breadth amounts, as was shown by other experiments, to about 0·25 volt.

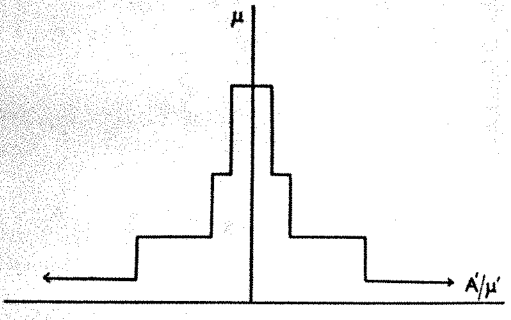

FIG. 1.

Errata : There was a mistake in the calculations for μ_B and the energies of the levels iodine and bromine (18 min.) in our letter in NATURE of May 30, p. 905. The correct values are : Iodine, $\mu_B = 0{\cdot}7$, energy $= 75 \pm 15$ volts. Bromine (18 min.) $\mu_B = 0{\cdot}35$, energy $= 300 \pm 80$ volts. The results for silver and rhodium are correct.

The Crystal Photo-effect and Rectifying Action in the Bulk of the Crystal

ATTEMPTS have been made to discover how far a rectifying action is connected with the crystal photo-electric effect (Dember effect). A. and A. Joffé have already suggested[1] asymmetry of the photo-electric current due to the illumination of one electrode.

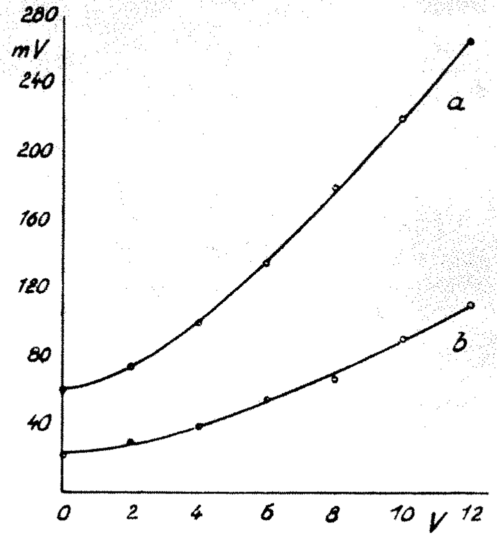

FIG. 1.

In our investigations, two electrodes, free from any obstructing layer, were attached to a cuprite crystal so that by the illumination an E.M.F. appears on them in consequence of the Dember effect. These electrodes were connected through two condensers with an alternating current source; the current flowing through the crystal caused an additional direct voltage as soon as the crystal was illuminated. In darkness, however, the alternating current did not cause any direct voltage. By exchanging the direction of the light both the Dember effect and the direct voltage, caused by the alternating current, changed their direction.

In Fig. 1, the resulting voltage, measured with an electrometer, is shown in relation to the alternating voltage applied to the crystal. In curve *b* the intensity of illumination was a quarter of that of curve *a*. Hence the intensity of the new appearance is related to that of the Dember effect. The value of direct voltage at the alternating voltage zero corresponds to the crystal photo-effect.

Several trials have proved that this appearance is caused by events in the bulk of the crystal (bulk-rectification) and not by the obstructing layers between the planes of the crystal and the electrodes. Moreover, rectifying action, caused by exposure to light, could not be formed in synthetic cuprous oxide, in which the Dember effect does not appear.

A Protective Action of Progesterone on the Genital Organs of Male Mice

IT is recognized that œstrone and progesterone are mutually antagonistic in some of their biological capacities. A fresh example of this antagonism has recently been observed at this Institute. Sixteen male mice, eight of which had been previously castrated, were given œstrone twice a week by cutaneous applications of a 0·01 per cent solution in benzene. On every day following these applications, progesterone was given to some by subcutaneous injections of 0·1 c.c. of a 0·1 per cent solution in sesame oil, to others by the application to the skin of a 0·1 per cent solution in benzene. The mice died or were killed at intervals from the 28th to the 120th day of the experiment.

After death, all the castrated mice showed the usual effects of œstrone, namely, keratinization of the coagulation gland, with arrest of secretion and epithelial hyperplasia in the seminal vesicle and prostate. The eight non-castrated mice, with one exception, showed none of these characteristic effects of œstrone. Spermatogenesis was in progress, the coagulation gland, seminal vesicle and prostate were normal in appearance, and in two instances normal ejaculation plugs were observed at death. In the exceptional case the mouse, which had been treated by cutaneous applications of progesterone, was killed on the 73rd day, and showed defective spermatogenesis, keratinization of the coagulation gland and loss of secretory function with epithelial hyperplasia in the seminal vesicle and prostate.

The difference between the results in the castrated and the non-castrated mice may perhaps be attributable to a combined effect in the latter of progesterone plus the testicular hormone. However this may be, it seems clear that progesterone can protect the genital organs of non-castrated mice from the injurious effects of excessive dosage with œstrone. In this connexion the similarity of molecular structure between progesterone and testosterone will be recalled.

For the progesterone used in this experiment we have to thank Prof. Schoeller of the Schering-Kahlbaum, A.G. of Berlin.

Determination and Excretion of Flavins in Normal Human Urine

KOSCHARA[1] has demonstrated the presence of flavins in urine, and has been able to isolate a crystalline flavin (uroflavin). I have carried out an investigation to determine if large doses of flavins (ox liver), similar to vitamin C (Harris[2] and van Eekelen[3]) and B_1 (Harris[4]), caused an increased urinary output.

The quantitative determination of the flavins in urine was carried out in the following way (details will be published elsewhere):

(1) Adsorption with lead sulphide. The lead sulphide was previously prepared, washed out and added to the urine. This was found to be preferable to the method generally used (addition of lead acetate to the flavin solution and introduction of hydrogen sulphide).

(2) Elution with a mixture of water-pyridine-glacial acetic acid (8 : 2 : 0·2).

(3) Oxidation with potassium permanganate in acetic acid solution and determination of the resulting colour with the stuphometer (*S* 47).

In normal urines (males), a daily urinary output of 819–1250 γ was found. The excretion per hour during the different periods of a day was found to vary between 30 γ and 50 γ.

Two subjects *A* and *B* (analysts) consumed cooked ox liver (100–140 gm.). Subject *A* took 5710 γ flavin[5] and excreted during 24 hours after the intake 3283 γ (normal excretion 952 γ), whereas subject *B* took 4240 γ and excreted 1797 γ (normal excretion 885 γ). The largest excretion per hour was observed two to three hours after the intake of the liver (subject *A*, 378 γ; subject *B*, 139 γ).

From these investigations, which took place in June, it follows that an increased excretion of flavins in urine took place after consumption of liver, probably caused by a 'saturation' of the subjects with flavins.

Further investigations are in progress.

Ultracentrifugal and Electrophoretic Studies on Antibodies

MANY attempts have been made to obtain from immune sera, substances carrying the antibody function. Protein solutions specifically precipitable to the extent of 40–60 per cent (nitrogen precipitated by pneumococcus specific polysaccharide/total nitrogen) have thus been prepared by the Felton method[1]. By dissociation of specific precipitates with strong sodium chloride, antibody solutions precipitable to the extent of 90 per cent have been prepared[2]. An investigation of the physico-chemical properties of these systems, especially of those bearing upon chemical homogeneity and the relation to the components of normal sera, would seem to be of interest.

To this end, preparations of horse and rabbit antibodies against pneumococcus type specific polysaccharides, as well as rabbit antibody against crystallized egg albumin, have been studied by ultra-centrifuge and electrophoresis methods[3,4], together with whole and fractionated normal sera. The simplest behaviour was shown by a horse serum preparation of type I pneumococcus anticarbohydrate[2] in which 61 per cent of the nitrogen was specifically precipitable. This showed almost homogeneous sedimentation, with sedimentation constant $s_{20} = 17 \cdot 2 \times 10^{-13}$ as compared with that of normal globulin from mammalian sera, s_{20} about 7×10^{-13}, previously found at Uppsala. However, normal sera regularly contain small amounts of a minor component of sedimentation constant about 17×10^{-13}. The electrophoresis of the above antibody preparation was homogeneous, with an isoelectric point as acid as *p*H 4·8.

In the case of rabbit sera, homogeneous sedimentation was found with no appreciable difference between the sedimentation constants of the globulin fractions of normal serum and immune serum, or of normal globulin and immune globulin containing up to 50 per cent of anti-egg albumin, or of antibody to the type III pneumococcus polysaccharide containing 90 per cent of precipitin[2], all showing s_{20} about 7×10^{-13}. Only the last mentioned preparation was investigated electrophoretically, giving inhomogeneous migration and an isoelectric point of about *p*H 6·6.

Preparations from antipneumococcus I horse sera (Felton) showed the same principal component as did the horse antibody above, together with varying amounts of slower and faster sedimenting components; whereas a Felton solution from *normal* horse serum was quite different, with a predominating component of $s_{20} = 7 \cdot 8 \times 10^{-13}$. Electrophoresis was rather inhomogeneous, with isoelectric points of about *p*H 5–5·2 for the immune and *p*H 5·7 for the normal preparations.

In a few runs with horse antibodies, the centrifuge was stopped when all of the heavier components had settled to the bottom, although a considerable amount of the lighter substances were still in solution. Samples taken out indicated that almost all specifically precipitable protein was on the bottom, showing that the antibody function is connected with the heavy component. This is also in accordance with previous experiments[5,6].

Preparations made from antipneumococcus horse sera, preserved with phenol and ether, although containing up to 87 per cent specifically precipitable nitrogen, were characterized by their inhomogeneity both in the ultracentrifuge and in their electrophoretic behaviour. The isoelectric point was *p*H 5·9, but a component of an isoelectric point of about *p*H 4·9 was also present.

From these data it is evident that protein preparations from immune sera carrying a high percentage of the antibody function may show all the signs of being chemical individuals, so far as the methods referred to are decisive. Nevertheless, methods of preparation and preservation may considerably influence the result (by denaturation ?) and give rise to less uniform systems, which, however, may still show a very high specific precipitability. It is also clear that different fractions of the serum proteins carry the antibody function in the horse and in the rabbit. It would thus appear that the rabbit produces antibody from the principal globulin component, while the horse develops pneumococcus I anticarbohydrate, at least, from an otherwise minor component.

The analytical methods for determining the antibody content of the solutions have been described in earlier publications[7]. Details of the experiments will be given and some of the many questions raised by this work will be discussed in forthcoming communications.

Two Unusual Modifications of Eye Colour in *Drosophila melanogaster*

IN the course of a series of investigations now in progress concerning the modification of eye colour in the fruit fly *Drosophila melanogaster* under X-irradiation, undertaken in connexion with an attempted determination of the volume of the locus 'white', two changes of colour have been observed which seem of sufficient interest to be worthy of a note at the present time.

The first change involves an apparent reverse genovariation, under X-irradiation, similar to those observed by Timofeef-Ressovsky[1], the change being from white to red eye.

The white stock concerned was obtained by suitable breeding from a few white individuals arising as spontaneous mutants in a pure culture of Florida wild-type *Drosophila* obtained about two years ago through the courtesy of Dr. Demerec. It has been bred for three months in this laboratory in pure culture, and has behaved in every way like typical white. It is, characteristically, completely recessive.

In the course of an investigation of morphological effects arising under X-irradiation, eggs and young larvæ from this white stock were exposed in considerable numbers to the unfiltered radiation of a Coolidge X-ray tube operated at 85 kvp. and 10 ma., the focal distance being five inches, with a wood backing. The tube was of lead glass with a thin sodium-glass window. The output of the tube was determined as 79·0 r./min. at the point of exposure of the material, a Victoreen dosimeter being employed. We are indebted to Dr. J. C. Hudson, of Cruft Laboratory, for this dosage measurement.

A total of 786 flies was examined from irradiated eggs and young larvæ. Among these were found two full reversions to Florida wild-type. It is believed that sufficiently elaborate precautions were observed in the technique adopted for irradiating and culturing the flies, so that the possibility of contamination from wild-type individuals was eliminated with reasonable certainty. No such reversions were observed in more than five thousand control individuals.

The second modification of interest arose in the stock of a culture of eosin *Drosophila* obtained from Turtox Service. Among more than 30,000 individuals examined, four were found in which a mutation to a colour considerably darker than eosin, but lighter than wild-type, was observed. We do not feel competent to name the colour modification. A single individual of the four constituted a mosaic representing a change which must have occurred very early in the development of the optic *anlage*, one eye of the fly being completely modified to the darker colour, the other typically eosin. Three of these individuals occurred in stock which had been irradiated under the same conditions as those stated above, but one was obtained from control populations grown on very old and highly infected molasses – corn meal agar medium. A very similar modification was independently observed by Dr. A. G. Richards, of the University of Rochester, and one of us, in control stock of a pure culture of eosin, obtained through the courtesy of Dr. Pincus, of Harvard University, and similarly held over old, depleted and infected banana – agar medium.

The modification seems of considerable interest in its further confirmation, not only that changes of whole eye colour may proceed from lighter to darker shades, but also that the wild-type condition is not necessarily the end-point of such a change. Again, sufficient care was used in handling the cultures, it is believed, to have eliminated the possibility of any contamination from an outside source with reasonable certainty. The change, indeed, was detected independently in three laboratories, at Rochester, Cambridge and Schenectady, and in none of these were stocks of similar eye colour present.

The 'Road Runner' of North America

ONE of the most remarkable and interesting birds of the arid portions of North America is the road runner (*Geococcyx californianus*), a ground cuckoo, which is often seen running in the road, sharing this habit with the killdeer plover (*Oxyechus vociferus*). The genus extends southward to Nicaragua, being represented in that region by another species (*Geococcyx affinis*). The accompanying illustration (Fig. 1) of a road runner attacking a rattlesnake, was furnished by Mr. G. A. Pearl of Garden City, Kansas. He got it from a travelling photographer whose name he does not know. Mrs. Merriam Bailey states that in the stomach of a single road runner, taken in New Mexico, were a large black cricket, a number of big grasshoppers, remains of a caterpillar and some beetles, a centipede six inches long and a garter snake a foot long.

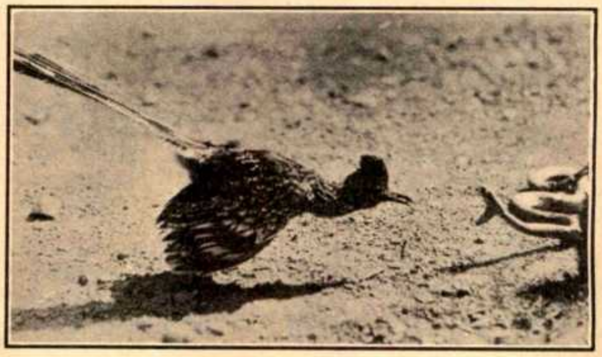

FIG. 1.

The road runner was described by Lesson in 1829, but Pike in 1810 refers to a strange new bird, which from his vague account must apparently have been the road runner.

Ascent of Air in Cyclones

A RECENTLY completed investigation on cyclones has led, amongst other results, to one which throws an interesting light on a long-standing problem. One of the deductions of W. H. Dines from soundings of the upper air was that the air in the troposphere in depressions, particularly between 4 km. and 9 km., is on the average cold for its level, though this air is, on the whole, ascending. The paradox is to explain by what agency the ascent of relatively cold air is maintained. Dines's results related to depressions crossing the British Isles or Western Europe, that is, to depressions which as a rule were in the later stages of their existence.

The present investigation shows that in a number of such depressions the structure comprises an outer region in which the average air speed varies inversely as r (r being distance from isobaric centre), and an inner region (at least in the polar air part) in which air speed varies directly as r. The existence of the outer simple vortex region is consistent with motion developed by convergence towards a central area :

the mathematical theory of the motion developed in this way was given by Rayleigh[1] in 1917, in explanation of the model cyclones devised by Aitken[2]; the mathematical theory was extended by Brunt[3] in 1921 to apply to motion on a rotating earth.

The inner regions generally are found not to be examples of 'solid spin', at least in the lowest 2 km. of the atmosphere, but rather, in certain parts, regions of specially marked convergence. In brief, it is found that—below the 2 km. level—convergence towards the centre goes on, roughly with complete conservation of moment of momentum up to a certain distance (which in different cases varies from 300 km. to 500 km.) from the centre, and then—in place of conservation—there is, instead, as the air enters the inner region. a gradual fall of speed with closer approach to the centre.

The total inward flux of kinetic energy across the periphery of the inner region is so considerable—speeds at this periphery being commonly of the order of 40 m.p.h.—that a question naturally arises as to what work is being done to account for the loss of kinetic energy by the air in the course of its closer approach to the centre. The obvious explanation is that here is the work required in the later stages of the depression's life to raise bodily the large central core of troposphere which, by reason of continued ascent, has become colder, level for level, than its environment. Calculation in a typical case indicates that about half the probable inward flux of kinetic energy below the 2 km. level would suffice to keep the core above this level moving upward until it had become on the average about 7° C. colder, level for level, than surrounding regions. This result, therefore, explains the manner in which depressions can continue in being until they acquire temperature characteristics which have hitherto seemed paradoxical, more especially in regard to any theory of origin in which convection may have played a part.

In one exceptional case—a vigorous and still developing system with a long course still to run—the feature characteristic of the inner regions of the other depressions was not developed, at least at the time when the depression crossed the British Isles. In this depression by contrast, a high wind speed was found up to relatively near the centre.

Transmission of High-Voltage Impulses at Controllable Speed

SIR J. J. THOMSON[1] first observed that if a difference of potential was applied to the ends of a long discharge tube (by an induction coil) the luminosity traversed the tube with a finite velocity. When either a positive or negative impulsive potential is suddenly applied to one end of a discharge tube while the other end is maintained at ground potential, one of us[2] found that the luminosity traversed the tube from the high-voltage electrode to ground. Immediately following this, a luminosity frequently traversed the tube from the ground back to the high-voltage electrode. A similar type of propagation of luminosity has been observed in a million volt spark between point and plane by Allibone and Schonland[3] and by Schonland and others[4] for certain types of lightning flashes. In order to obtain more information about the initial breakdown in gases, we have undertaken an investigation of the propagation of potential in long discharge tubes when impulsive voltages are applied to one end of the tube while the other end is earthed.

By means of a high-speed cathode ray oscillograph, it was found that in the case of both positive and negative applied impulses, a definite potential wave traversed the tube from the high-voltage electrode to the earthed electrode, immediately followed by a much faster return wave from ground back to the high-voltage electrode. In the case of the initial impulse, the wave velocity, wave form, voltage attenuation and energy carried in the wave front were measured and found to vary with both pressure and applied potential. A few values for the speed of the initial impulse in a 5 mm. glass tube containing air are shown in the accompanying table.

Applied Voltage (kv.)	Pressure (mm. Hg.)	Speed of Impulse (cm./sec.)
+127	0 08	9×10^8
+127	0 24	43×10^6
−125	0 08	15×10^8
+171	0 17	27×10^8
+ 74	0 017	$5{\cdot}4 \times 10^8$
+ 74	0 24	14×10^8

For the greater applied potentials the voltage wave showed no observable distortion or attenuation, at least for lengths of tube less than 10 metres. However, at 74 kv. and the higher pressure (0·24 mm.), the voltage wave was very much flattened. For the 170 kv. and 74 kv. applied impulses with 0·025 mm. pressure in the tube, the maximum current during the initial wave was 429 amp. and 146 amp. respectively. In addition to the information the above results give as to the nature of the initial breakdown in gases, they show that a discharge tube may be used as a transmission line in which the velocity of propagation of the voltage wave is easily controllable over quite wide ranges. This type of transmission line should be of use in many problems[5] where it is necessary to transmit high-voltage impulses from point to point at predetermined velocities less than that of light.

The detailed results of this experiment will be submitted for publication elsewhere. We wish gratefully to acknowledge a grant from the American Philosophical Society, which has made this work possible.

Narrow Continuous Band of Potassium in the Extreme Red

ALTHOUGH the absorption bands which appeared, as reported by Kuhn[1] and Datta[2], near the principal series lines of potassium at high vapour pressures were interpreted on the assumption of polarisation of the molecule, the bands which may have appeared near the resonance lines λλ7699, 7665 were not observed.

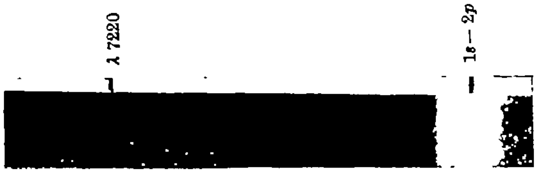

FIG. 1.

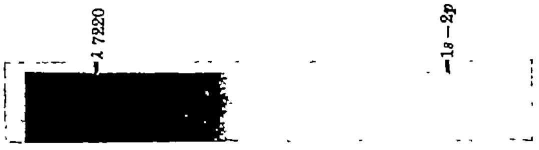

FIG. 2.

With the view of searching for these bands, the extreme red absorption spectrum of potassium vapour was investigated. By heating the potassium metal in a steel tube filled with hydrogen to a pressure of about 10 cm. mercury, spectral photographs of the potassium vapour were taken at the first order region of the 1·5 m. concave grating. When the continuous light from a carbon arc passed through the vapour, keeping the temperature sufficiently high, a remarkable broadening of the resonance lines, as shown in Fig. 1, was observed. At higher temperatures a narrow continuous band appeared at about λ7220 (Fig. 2), while Fig. 3 shows its photometer curve. In the absence of hydrogen this band was also observed, but with difficulty.

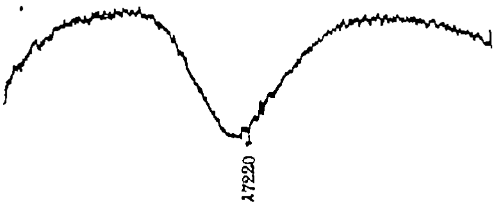

FIG. 3.

Wurm[3] reported a narrow band of sodium appearing on the shorter wave-length side of the *D*-lines, explaining it by assuming polarization of the molecule. Hamada[4] observed the fluctuation of a continuous band in the same region, considering its origin as the sodium quasi-molecule. The potassium λ7220 band may be interpreted in the same manner.

Though the longer wave-length side of the potassium resonance lines was also photographed, the absorption of the $A^1\Sigma \rightarrow B^1\Sigma$ band was so strong that any narrow continuous band was difficult to observe.

Liquids of High Refractive Index

IN a previous letter to NATURE[1] under this title, we gave values for the refractive index of phenyldi-iodoarsine as measured by us. Our attention has now been directed to the fact that the properties of this compound had already been accurately measured and published in a valuable paper on "The Optical Properties of Arsenic" by Gryszkiewitz-Trochimowski and Sikorski[2] which had appeared six years previously. We had unfortunately overlooked this paper owing to the fact that in none of the abstracts or collective indexes which we consulted as a guide to the relevant literature was there any mention of the above compound in connexion with these authors. The figures for phenyldi-iodoarsine given by the Polish workers ($n_D^{14\cdot5}$ 1·8527 ; $d_4^{14\cdot5}$ 2·6264) are higher than those we communicated, but agree closely with those we have recently obtained with the purer samples now commercially available.

We take this opportunity to add a warning note. Though we occasionally use phenyldi-iodoarsine when refractometer readings of high index are required, the action of this liquid on the soft glass hemisphere of the instrument is distinctly deleterious. The chief usefulness of this remarkable compound will thus probably be as an immersion medium.

Structure of Bromine III

IN a previous letter[1] it was reported that the structure of Br III was detected, the intervals of the fundamental term 5*s* ^4P being 2589 cm.$^{-1}$ and 2253 cm.$^{-1}$. A further comprehensive investigation, carried out particularly to distinguish between the lines of Br II and Br III, has led to a considerable extension of the scheme, which consists of doublets and quartets of the 4*p*, 5*p*, 5*s*, 4*d* and 5*d* configurations. On account of the large intervals of the 4*d* and 5*d* configurations, it is difficult to assign the *L*-values to these terms. Assuming an arbitrary value of 300,000 cm.$^{-1}$ for 4*p* $^4S_{1\frac{1}{2}}$, some of the chief term values are :

5*p* $^4D_{\frac{1}{2}}$	126823	5*p* $^4P_{1\frac{1}{2}}$	121875
5*p* $^4D_{1\frac{1}{2}}$	126165	5*p* $^4P_{2\frac{1}{2}}$	119751
5*p* $^4D_{2\frac{1}{2}}$	124095	5*s* $^4P_{\frac{1}{2}}$	154588
5*p* $^4P_{\frac{1}{2}}$	123335		

The intervals of 4*p* ^2D and ^2P are found to be 1259 cm.$^{-1}$. and 1665 cm.$^{-1}$ respectively. About 200 lines of Br III have been classified altogether.

The complete analysis is being communicated to the Royal Society of London.

Preparation of Lithium Alum

DURING some work on the mass susceptibility of the alums, a successful attempt was made to prepare lithium alum, despite the fact that its existence and even the probability of its existence has been repeatedly denied.

Molecular proportions of the monohydrate of lithium sulphate and the octadecahydrate of aluminium sulphate were dissolved in the minimum quantity of cold water. The solution was concentrated considerably by evaporation on a sand bath and cooled in a freezing mixture of ice and salt with vigorous stirring, when it crystallized suddenly and deposited a mass of very soft small crystals, which were filtered and dried at the pump and afterwards on porous plates. The mother liquor after a further slight concentration deposited small hard transparent crystals on keeping in the freezing mixture.

Both crops of crystal contain 49·00 per cent of water ($Li_2SO_4Al_2(SO_4)_3.24H_2O$ requires 48·93 per cent water). The crystals are isotropic, a combination of cube and octahedron. On keeping at ordinary temperature, or on warming a few degrees, they decompose and the salts dissolve in the liberated water. They are exceedingly soluble in water; they lose the whole of the water at 200° C. and swell to a bulky friable mass. The mass susceptibility is $-0{\cdot}541 \times 10^{-6}$ and molecular susceptibility -479×10^{-6}. The properties of the alum are under investigation.

Points from Foregoing Letters

DR. A. S. RUSSELL describes work which suggests that metals of the class which forms compounds with metals of the copper, iron, cobalt and nickel class may be arranged in a list analogous to the electrochemical series. Any metal in this list can displace from intermetallic combination one lower in the list.

The formation of long carbon dendrites has been observed by K. D. Luke and Drs. W. M. Madgin and H. L. Riley in the cathodic reduction of colloidal solutions of graphitic oxide. Colloidal particles of graphitic oxide are negatively charged, and the reduction occurs in spite of the strong repulsive forces which must exist in the neighbourhood of the cathode.

The large majority of the negative ions formed during electric discharge in mercury vapour, hydrogen, nitrogen and carbon dioxide, Dr. F. L. Arnot finds, do not arise by the attachment of one electron to a neutral atom, but by the attachment of two electrons to a positively charged ion. The author calculates the probability of such conversion from positive into negative ions, for the gases mentioned above, at the surface of a negatively charged nickel electrode.

From the energy of the neutrons selectively captured by rhodium, Drs. P. Preiswerk and H. von Halban, jun., deduce the distance, breadth and form of the nuclear levels in that element. The data required were obtained by determining the absorption coefficient for each additional layer of rhodium.

Light falling upon a cuprite crystal in contact with two electrodes through which an alternating current is passing, produces an additional direct voltage. Dr. G. Groetzinger and J. Lichtschein submit curves showing how the resulting direct voltage varies with the alternating current, and its relation to the crystal photo-electric effect. They consider that this additional current is connected with events taking place in the interior of the crystal.

Experiments on mice carried out by H. Burrows indicate that progesterone, a substance related to the male sex-hormone testosterone, can protect the genital organs of the non-castrated animals from the injurious effects of large doses of the female sex-hormone, œstrone.

An increased excretion of the yellow pigments, flavins, in the urine, after eating cooked ox-liver, is reported by A. Emmerie.

From the rate of sedimentation and the movement in an electric field (electrophoresis) of the protein particles from horse serum carrying an anti-body, Prof. M. Heidelberger, Kai O. Pedersen and Arne Tiselius conclude that the particles are of uniform size and possibly a definite chemical compound. The sedimentation constant is $17{\cdot}2 \times 10^{-13}$, and the anti-body is apparently formed from a heavier minor component of the protein. The rabbit anti-body against crystalline egg-albumin, on the other hand, is produced from the principal globulin component.

Two unusual modifications of eye colour in the fruit fly, under X-ray irradiation, are reported by Dr. E. V. Enzmann and C. P. Haskins. In one case the change was from white to red, involving apparently a reverse genovariation; in the second case mutations in a culture of eosin *Drosophila* produced eye colour considerably darker than eosin, showing that wild-type condition is not necessarily the end-point of change from light to darker shades.

In the centre of a 'depression', in the later stages of its existence, the air at a height of 4–9 km., though colder and therefore heavier than surrounding layers, is nevertheless ascending. The energy needed to lift it, Dr. A. H. R. Goldie suggests, is provided by the winds, which give up part of their energy and slow down as they converge spirally towards the centre of the depression.

The propagation of voltage impulses in long discharge tubes has been investigated by Dr. L. B. Snoddy, Prof. J. W. Beams, W. T. Ham, jun., and H. Trotter, jun. The tube was found to be an excellent transmission line for high-voltage impulses. The velocity of propagation was easily controllable over quite wide ranges of the order of 10^8–10^9 cm. per sec.

A broadening of the resonance lines in the extreme red of the absorption spectrum of potassium vapour in the presence of hydrogen gas is described by T. Okuda, who considers it due to the polarization of the molecules.

ERRATUM. Dr. C. H. Douglas Clark, referring to the paragraph in this column (July 18) on his letter "Optical Polarization Ellipsoids of the Hydrogen Halide Gases", states that it is the polarizability along the long axis which is equal to that of the corresponding negative ion.

Research Items

Pre-Crag Flint Implements

THE evidence bearing on the age of the implements of flint which since 1909 have been found in the Suffolk bone bed has been reviewed by Mr. J. Reid Moir in the light of the conclusions to be drawn from patination, from forms and flaking, and from condition (*J. Roy. Anthrop. Inst.*, 65, Pt. 2; 1935). It is argued that just as in a Pleistocene deposit implements can be sorted out according to their types and assigned to their appropriate age, so in a Pliocene deposit it is legitimate to treat them in a corresponding way. By observing the differences in patination and the reflaking of the pre-Crag flints, it is possible to divide them into five groups; and this classification is supported by an examination of form. Group 1, for example, is rich in implements of the Harrisonian eolithic type, made chiefly from primitive and coarsely shaped implements; but being made from primitive flake implements, they show an advance in technique on the true Harrisonian eolith, which was made from pieces of naturally broken tabular flint. In all the other groups, implements of this type are rare, showing that the production of artefacts of eolithic character ceased after the epoch in which implements of Group 1 were made. Of the rostro-carinates, the same proportion is present in Groups 1, 2, 3, but in 4 the proportion is much less, while in Group 5 none appears. In Group 2, where rostro-carinates occur in the same proportion as Group 1, the eolithic form, which is rare, is replaced by a whole series of racloirs, points, scrapers, choppers and other types. Group 5 is remarkable in being composed of 50 per cent racloirs and 50 per cent unclassifiable specimens. In the 363 specimens, only eight hand-axes are present, though the presence of one specimen in Group 1 shows that the knowledge how to make the hand-axe goes back a very long way. Taking the evidence as a whole, it is maintained that there are few who would deny that Group 1 is of very great antiquity but cannot represent the first attempt of man to shape flints; while Groups 2, 3 and possibly 5 are the most advanced. Group 4 seems to show a slight but very definite regression.

Fishes from the *Pawnee* Second Oceanographic Expedition

FOLLOWING his first and second reports (1928 *a* and *b*) in the same publication, Mr. C. M. Breder, jun., deals with the Heterosomata to Pediculati from Panama to Lower California (Scientific Results of the Second Oceanographic Expedition of the "Pawnee" 1926. *Bull. Bingham Oceanographic Coll.* Peabody Museum of Natural History, Yale University, 2, 1936). There is much interesting matter in this report, which includes many new species and observations. The new genus *Hubbsiella* is created to include *Menidia clara* Evermann and Jenkins, which differs from *Menidia* proper in several important characters, as has already been noticed by Jordan and Hubbs. Remarks on *Alectis hopkinsi* (Jordan and Starks) suggest that the Pacific representatives may lose their juvenile filaments of the dorsal fin normally by breakage, the stubs simply healing up and not regenerating. A useful key to the Eastern Pacific Hæmulidæ is given, containing twelve species belonging to nine genera.

Land and Freshwater Molluscs of Colorado

PROF. JUNIUS HENDERSON has enlarged greatly and corrected his original report of 1924 on this subject, and the present monograph, "Mollusca of Colorado, Utah, Montana, Idaho, and Wyoming—Supplement" (*Univ. Colorado Studies*, Vol. 23, No. 2, 1936), includes much new material. Careful work has been done upon Rocky Mountain molluscs during the past decade, resulting in a better understanding of many species and the addition of a number to the fauna, some of them new to science. In the comprehensive work now before us, we find a very large number of both land and freshwater forms listed and criticized, with valuable notes and, in some cases, figures and plates. All workers on mollusca in these districts will benefit by the publication of this most useful paper.

Animal Products

CHAPTERS vii and viii of the second part of the first volume of "Die Rohstoffe des Tierreichs" (Berlin: Gebrüder Borntraeger, 1935. 21.50 gold marks) deal with the hard substances produced by animals, ranging from fish scales, otoliths, tortoise shell and bird's claws to rhinoceros horns, antlers, bone and ivory. The second chapter treats of glue, gelatine and slime. Each product is considered historically, and its characteristics and treatment given. The data concerning its trade and the uses to which it is put are discussed. The full bibliography at the end of each chapter is subdivided into sections for each product. It is a most useful source of information.

Pathogenic Actinomyces

"THE Pathogenic Aerobic Organisms of the Actinomyces Group" is the title of a report by Dagny Erikson (Medical Research Council. Special Rep. Series, No. 203. London: H.M. Stationery Office. 1*s*. net). The study of fungi of medical importance has been hindered in the past by inadequate examination and description and by confused nomenclature. In this report, Miss Erikson has examined a number of strains of *Actinomyces* collected by Dr. A. G. Gibson from enlarged spleens in various clinical conditions, and a series of strains—variously labelled *Actinomyces*, *Streptothrix*, *Nocardia*, etc.—contained in the National Collection of Type Cultures, maintained by the Medical Research Council at the Lister Institute, London. The cultural, morphological and biochemical characters of twenty-five species are described, including fifteen that appear to be entirely new forms.

Testing Green Karri Timber

UNDER the auspices of the Council for Scientific and Industrial Research of the Commonwealth of Australia, the Division of Forest Products is undertaking an extensive series of tests on the mechanical and physical properties of the timber of karri (*Eucalyptus diversicolor*). Several special tests have so far been carried out ("A Discussion of Special Tests on the Compressive Strength of Green Karri" by Ian Langlands, Division of Forest Products, Pamphlet No. 61—Tech. Paper, No. 19. Government Printer, Melbourne, 1936). It is shown in this paper that green karri will withstand greater stresses perpendicular to the grain when the load is applied to the tangential face than when it is applied to the radial face. The modulus of elasticity of karri is also much higher when the load is applied to the tangential face. The influence of the width of the loading plate on the compressive strength perpendicular to the grain is considered in detail. The results are given of a series of tests on green karri which were carried out to check the applicability to this species of a rational formula suggested by the U.S. Forest Products Laboratory for northern hemisphere timber. The tests showed that the formula applies very closely when the stress at 1/10 in. deflection is considered; but if the stress at the limit of proportionality is taken as the criterion, the agreement is not so good because of unavoidable eccentricities in loading.

The Japanese Earthquake of February 21, 1936

THOUGH it did not attain more than semi-destructive intensity, the Kawati-Yamato earthquake of February at 10h. 8m. (1h. 8m. a.m., G.M.T.) ranks as the strongest felt in central Japan since the Tango earthquake of 1927. It is described in three short papers published in vol. 14 of the *Bulletin* of the Earthquake Research Institute. Messrs. N. Nasu and T. Hagiwara (pp. 285–289) study the early after-shocks, of which there were 77 during the first 24 hours. A network of five seismological stations was formed around the epicentre near Mt. Hutagami, from the records at which it was found that the focal depths of five after-shocks during the first fortnight were less than six miles. Mr. N. Miyabe (pp. 297–306) remarks that earth-sounds were heard at many places, but they seemed to come as a rule from the nearest mountain rather than from the epicentre. Lights were noticed with the earthquake by several persons, but it is not certain that they were connected with it. Mr. T. Saita (pp. 307–317) examines the relation between the amount of damage and geological structure. He states that, on hard ground, heavy buildings collapsed seriously, while, on soft ground, old and poorly built houses were much damaged.

A Piezoelectric Ultra-micrometer

THE ultra-micrometer is an instrument for the measurement of linear displacements smaller than those which can be measured by optical interferometry; these are limited by the wave-length of light. Whiddington in 1920, using two oscillating electrical circuits tuned so as to produce an audible beat tone, was able to extend the sensitivity of measurement to a value smaller than 10^{-8} cm. Later on, W. G. Cady and D. W. Dye used a piezo-electric quartz plate instead of a resonant electrical circuit. In *Science* of May 15, Prof. J. C. Hubbard describes how by using a quartz plate of 600 kilocycles resonant frequency, a frequency change of one sixtieth of a cycle may be detected. This corresponds to a frequency change of about three parts in one hundred million. To test the method, a micrometer condenser has been constructed so that each plate is attached to a separate support clamped to a heavy steel rod. Adjustments are provided for making the plates parallel and for making relatively large variations of plate distance by means of a micrometer screw. A variable condenser in parallel is provided so as to operate the micrometer condenser at any desired plate distance and thus secure a wide range of sensitivities. In the experiments which have hitherto been carried out, displacements of 10^{-8} cm. have been measured with an inaccuracy less than a few per cent, although no special precautions were taken against mechanical disturbances. It is hoped that by taking such precautions, displacements of 10^{-10} cm. may be measured. The attainment of a sensitivity of this order should open a new avenue of approach to many important and interesting problems in atomic and molecular physics.

Bakelized Bearings

AN extraordinary development in the kind of bearings used in machinery intended for heavy service is described in the *Metropolitan-Vickers Gazette* of July. The provision and maintenance of bearings in rolling mills is more difficult probably than in any other industry. The pressures are high, the conditions are usually dirty, and maintenance and replacements are difficult and expensive, both in cost of spares and in time lost while repairing or changing. For the heaviest service, white metal bearings have been found quite inadequate. Bronze bearings, usually called brass, are commonly used, but the wear is very rapid. Much thought has been given to this problem, and after many attempts an apparently most unlikely solution has proved the best. It has been found that a bearing material consisting of a fibrous substance like paper or cloth bonded with 'bakelite', a synthetic resin, is far better for this service than any metal. Also, no oil is used, but the bearing is fed continuously with a stream of water. The water has a dual function; in the first place it acts as a lubricant, and in addition it fulfils a more important function by keeping the bearing cool. Cooling is specially required in bearings of this kind, owing to the fact that the heat conductivity of the bakelized bearing material is very much smaller than that of metal. A stream of water is found the best means to carry away the heat generated by friction. A very large number of these bearings are already in service and give good results. The saving in power varies from 30 to 60 per cent, the life is increased about ten times, and there is a saving in the workers' time, as there is seldom need to adjust the rolls.

Relativistic Problem of Two Bodies

THE present verifications of the general theory of relativity deal only with gravitational fields due to a single body. For example, in the case of the advance of the perihelion of Mercury, the field is considered as due to the sun alone, an approximation which is legitimate owing to the smallness of the ratio of the mass of the planet to that of the sun. Prof. T. Levi-Civita (*L'Enseignement Mathématique*, 34, 149; 1935. Paris: Gauthier-Villars), deals with the corresponding problems for two bodies of comparable mass. The equations of relative motion, to a certain degree of approximation, show that we may speak of a central force separable into a Newtonian attraction and an Einsteinian perturbation, which produces an advance of perihelion. This might have been expected, but it is strange to find that the centre of gravity oscillates slightly instead of being at rest or moving uniformly in a straight line. There seems no hope of testing this by observation, but the new formula for the advance of perihelion (slightly different from that applicable in the case of Mercury) may possibly be verified by observation of double stars.

Museums Association

ANNUAL CONFERENCE AT LEEDS

THE forty-seventh annual conference of the Museums Association was held at Leeds on July 6–10. The meetings were held in the Museum, and the usual trade exhibition and members' exhibits were in the entrance hall of the Art Gallery. The conference attracted a record attendance; more than three hundred members and delegates met under the presidency of Sir Eric Maclagan, director of the Victoria and Albert Museum.

Sir Eric, in his presidential address on "Museums and the Public", gave a summary of the various services afforded children and adults by the museums. He is not convinced that children's museums, as separate entities, are a wise ideal, and preferred that children's exhibits should constitute a bait rather than a permanent diet. He would like to see the abolition of many petty restrictions upon adults, such as the ban upon walking-sticks and umbrellas; yet, on the other hand, there is the danger of coddling the public owing to the excellent seats, gardens, refreshment rooms and guide lecturers now at the service of the visitor. Too little, perhaps, is being left to the public, and museums are not peep-shows and need not degenerate into them. In view of the little that museums do which has any real news value, Sir Eric thinks that great credit should be given to the newspapers, which are so often among the museum's best friends.

Following the presidential address, Col. Kitson Clark told the interesting story of the various Leeds museums and the persons responsible for their foundation. The morning session concluded with an address by Sir Harry Lindsay, director of the Imperial Institute, upon the various methods of visual instruction developed and used for adults and children in the Institute.

In the afternoon, Mr. F. R. Worts, headmaster of the City of Leeds School, dealt with museums and secondary schools, a subject which elicited a lively discussion, from which it was apparent that too much is expected from the museums and too little co-operation offered by the schools. The session concluded with a somewhat detailed, but important, discussion on nomenclature in natural history collections, opened by Dr. F. J. North, and a description of the new Perth Museum and Art Gallery by its director. Mr. J. Ritchie, who illustrated his remarks with lantern slides and a cinematograph film.

The opening paper on Wednesday morning was by Mr. Leigh Ashton, of the Victoria and Albert Museum, who described the display methods he used so successfully in arranging the recent Chinese Art Exhibition at Burlington House. He was followed by Mr. Philip Hendy, director of Leeds City Art Gallery, who had much to say about the lack of civic encouragement to art galleries. He deplored the lack of visual imagination at the present time and the tendency to "think in print". He regrets the decay of craftsmanship, and looks upon the art gallery as a remedy to industrialism, but he thinks that art galleries might profitably exhibit more manufactured objects. Mr. S. F. Markham followed with an account of the museums in India, based upon his recent survey, and the morning session concluded with an important discussion on the copyright of paintings in museums and art galleries.

Thursday morning was occupied largely by the annual general meeting but there was a vigorous discussion on the future of the Association. Finally Dr. Mortimer Wheeler read an account, by Mr. Iliffe of the folk museum movement in Palestine.

Excursions were made to various places of interest including Temple Newsam Mansion, Kirkstall Abbey, Harewood House and Fountains Abbey.

The new president of the Association is Alderman Charles Squire, of Leicester, and the next conference will be held at Newcastle-upon-Tyne.

Society of Chemical Industry

ANNUAL MEETING AT LIVERPOOL

THE programme of the annual meeting of the Society of Chemical Industry at Liverpool, July 6–10, in itself provides an excellent illustration of the way in which chemical industry is linked up with almost every aspect of our national life, and of the extent to which chemical science enters into questions not only of industry but also of transport, food supply and the like.

The Messel Memorial Lecture, "Works as I have seen them Grow", delivered by Sir Robert Mond on July 8, gave an impressive account of the development of the Winnington works of Brunner, Mond and Co., as well as of the Mond Nickel Co. and the Mond Gas Companies, which well illustrates the creative power of science in developing new industries or adapting old ones to changed conditions. It might also be regarded as a dissertation on the theme that the mental process of pure research, the way of asking Nature the right question and of obtaining adequate responses, is as applicable to applied as to pure science. Knowledge of progress depends on trustworthy and continuous measurements of all the many factors involved, and these measurements can be effected as well on a works as on a laboratory scale, and with intelligent designing no great or specially expensive methods are required. Acting on this principle, Dr. Ludwig Mond not only made the Solvay ammonia-soda process a commercial and technical success, but also showed by what means the science of physical chemistry could be studied practically and developed in a works instead of in a laboratory.

Sir Robert Mond suggested that this was his father's great contribution to human progress, and those who took part in the numerous visits to works and factories during the week found much to justify Sir Robert's assertion. It was equally supported by papers presented to the meeting such as Dr. R. Houwink's address to the Plastics Group on "Synthetic Resins, their Formation, Properties and Possibilities", Dr. L. H. Lampitt's on "Food Package and the Consumer" at the Food Group Congress held jointly with the Royal Sanitary Institute at Southport, or Mr. R. G. Batson's address to the Road and Building Materials Group on "Scientific Research and the Highway Engineer".

All these papers and discussions emphasized the way in which exact measurements by physical methods are laying the foundations for future advance. Dr. Houwink, discussing future developments, said that one of the most urgent requirements is for stronger, more elastic, more shock resistant and electrically improved products, and referred to the possibility of improving the properties of shellac so that competition with resins like those of the phenol-formaldehyde type become possible again. Dr. Lampitt referred to the way in which growing public appreciation of the importance of hygiene has led to fresh demands for packing materials which the chemist has been able to meet.

The address for which the Liverpool meeting will be most remembered, however, is that of the president, Mr. W. A. S. Calder, on July 7, on "The Chemist as World Citizen". Mr. Calder linked up the chemist and his training to acquire and face facts with his wide responsibilities in the world to-day. One of the chief causes of the dangers to freedom and progress is the utter ignoring of facts, and Mr. Calder protested strongly that the chemist is not the destroyer which the irresponsible Press represents him to be. It is a lamentable fact, however, that we are all susceptible to the poisonous virus of newspaper propaganda. No one capable of thought can fail to admit that no one nation is ever entirely responsible for a war, and Mr. Calder pointed out that the training of a chemist should teach him the impossibility of being always right. Chemists cannot escape the responsibility of seeing that the danger of refusing to face facts is duly impressed upon our politicians.

Another direction in which the chemist can play a part as a world citizen is that of the prevention of accidents. The chemist and engineer are qualified by their training to be of special service in anticipating risks and thus preventing accidents. Many accidents still occur which could not be possible if those in charge of affairs fully realized their responsibility. Men are even exposed to unnecessary risks which they are expected to avoid by compliance with impossible orders for their own safety, and Mr. Calder expressed the hope that the interchange of details of accidents already taking place between several countries might become world-wide.

Coral Reef Ecology at Low Isles

THIS fine contribution* to the series of reports on the Great Barrier Reef Expedition of 1928–29 is chiefly concerned with accounts of three traverses across the reefs at Low Isles. Its production is the result of a collaboration between several workers; Prof. T. A. Stephenson originally chose the traverses; physical and chemical data were provided by Mr. A. P. Orr, and level sections by Mr. M. A. Spender. The bulk of the work, however, fell to Dr. Fraser and Dr. S. M. Manton, who jointly enumerated the organisms present, while the latter is responsible for drawing up this report.

Along each traverse a strip of reef one yard in width was examined. The first traverse, more than 1,000 feet long, started from a Thalamita flat inside the reef and crossing a shallow moat, passed over a boulder tract to descend the seaward slope of the reef to the muddy sea-floor at about twenty feet below datum. The second traverse, about half the length of the first, crossed a portion of the reef where the contour of the sea-floor was rather irregular. The third traverse on the windward side of the reef could not be worked in detail on account of the roughness of the water; but such observations as were made are nevertheless of much interest.

The results of these surveys are given in a number of graphs that permit easy comparisons to be made of the distribution of corals and algæ, both as regards abundance of individuals and of species. Algæ were abundant only in the moat and on the inshore part of the second traverse; they were almost absent from the seaward slopes of all three. Coral growth was vigorous in the deeper part of the moat—where there is always nearly a foot of water at low tide—as well as on the seaward slopes of the traverses below the datum line. In the moat physical conditions were extreme, especially as regards temperature and to a considerable extent silting; the association of species living there was hence not the same as that outside. *Montipora ramosa* was the dominant coral in the moat, indeed being restricted to that situation, whereas the *Acroporas*, species sensitive to heat and silt, were almost entirely confined to the seaward slopes.

One of the more important points brought out is the influence of silt on the distribution of corals. It seems clear that whereas some species are well able to withstand a fair amount of silting, others are killed off by very little. Silt is evidently a limiting factor, and it is in turn correlated, of course, with water movement.

In addition to the traverses at Low Isles, small isolated areas on the Outer Barrier Reef were examined and are described here for comparison.

---

* British Museum (Natural History). Great Barrier Reef Expedition, 1928–29. Scientific Reports, vol. 3, No. 10: Ecological Surveys of Coral Reefs. By Dr. S. M. Manton. Pp. 273–312+16 plates. (London: British Museum (Natural History), 1935.) 10s.

The different physical conditions there are primarily responsible for the change in the character of the fauna as compared with that at Low Isles.

This report is most beautifully illustrated by a series of large-scale maps in picture form, showing in detail the distribution of corals and other organisms on small selected areas of the traverses or on portions of the Outer Barrier Reef. These maps show evidence of lavish care and attention both in the preliminary drawings and in the measurements necessary to produce them, as well as in the skilful draughtsmanship that has produced the finished plates. They should be of great value to all students of coral reef ecology.

Diesel Fuels and Engineering

AT the first overseas meeting of the Institution of Petroleum Technologists held in Holland on May 8–11, a series of papers was read on diesel fuels and diesel engineering.

Among papers presented for discussion was one by Ir. W. Hupkes on "Diesel-Electric Traction on the Netherlands Railways". Of particular interest in this paper is a clear exposition of facts leading to selection of diesel-electric trains for the frequent and regular conveyance of passengers in the Netherlands. The triple-articulated diesel-electric engine chosen was designed specifically to meet circumstances of accommodation, coupling, speed, rapid acceleration and open-air storage when not in service. Full details are given of the car arrangement ultimately decided upon, motive power, performance, braking, automatic coupling, heating and ventilation.

Ir. G. J. Lugt in his paper on the "Design of Fuel Injectors for Diesel Engines" described the two methods of fuel injection, mechanical and pneumatic, and indicated the function of the injector as being the distribution of the fuel over the air in the compression space of the cylinder. He then devoted himself to closed mechanical injectors as being almost exclusively used by diesel engineers. He concluded with the remark that there is now little need for individual design of injectors for diesel engines as they have become to all intents and purposes a standard fitting.

Mr. C. H. Barton in his paper on "Diesel Fuel Specifications" pointed out the necessity for such specifications in the classification of fuels into grades and in the indication of desirable properties in particular grades. He described tests commonly adopted in fuel specifications and indicated their significance.

A joint paper by Ir. G. D. Boerlage, Ir. J. J. Broeze, L. J. Le Mesurier and R. Stansfield, on the "Correlation of Tests on the Ignition Quality of Diesel Fuels, carried out at Delft and Sunbury", was the outcome of differences found in the two laboratories regarding the rating in terms of cetene numbers of some commercial fuels. A great deal of work was involved before agreement was reached, and the results of this collaboration are of major importance as providing a feasible technique for the accurate determination of ignition quality of diesel fuels.

Training of the Engineer in the U.S.A.

A PAPER on the training of the young engineer by R. E. Hellmund, of the Westinghouse Company, just published by the American Institute of Electrical Engineers, takes into account the changing conditions of the industry recovering from the great depression. It was discussed at the summer convention of the American Institute of Electrical Engineers at Pasadena on June 26, 1936.

The disorganization of industry brought about in the United States and elsewhere by bad times has resulted in many radical suggestions being made in connexion with engineering education, and Mr. Hellmund has noted a tendency to discard good methods with bad. Even if it were desirable for the good of humanity to retard the introduction of labour-saving devices with the object of avoiding unemployment, it would not be advisable. Every engineer employed in any competitive industrial enterprise must, if the business is to survive, reduce costs by every means in his power. Even the greatest advocates of Government control have never suggested the elimination of competition in industry. He states that the only way the engineer can help to diminish unemployment is to create new products for which there will be a demand. This will enable costs to be reduced, and at the same time the population will benefit by the improvement. He suggests, therefore, that economics be given a more prominent place in engineering education. Psychology is another subject of study that will assist the engineer in carrying on his work effectively under modern conditions. The question arises, in what way should the syllabuses of the colleges be best altered so as to accomplish this.

Mr. Hellmund has noticed that young engineers in industrial organizations frequently become so absorbed in the solution of an interesting problem that they neglect to study its economic and commercial aspects. During the depression, it was more than ever necessary to focus attention on this side of the question. In many college curricula, courses in economics are included, but they are given by the department of economics, and much of the work covered at present is far removed from the practical applications encountered by the engineer in his everyday work. He concludes that the engineering schools should offer special abbreviated courses which show how the basic laws can be applied in practice.

Psychology is another subject that in several ways can assist the engineer in carrying on his work effectively. In industrial organizations, work cannot be done efficiently without a thorough knowledge of human nature. The depression has emphasized the importance of this. Although the study of psychology will not correct all personal shortcomings, yet it seems the only practical way by which the colleges can bring about improvement. A few specific lectures on this subject would be helpful in a school of engineering, but, at least at first, they should not be made compulsory.

Graduate courses at college prior to entering industry are, in Mr. Hellmund's opinion, only of limited value. It is dangerous for an engineering student to stay too long in a college atmosphere. The profession is one which requires courage and initiative, qualities which are rarely developed in college life by the type of students who take postgraduate courses. It is true that there are a few kinds of highly technical research work which might advantageously be done at a postgraduate course at the university. If the postgraduate work is undertaken because the graduate is unable to find immediate employment in industry, it is advisable not to take courses in the specific subjects of the branch of engineering contemplated but in affiliated subjects. For example, an engineer wishing to enter research work on electrical subjects would do well to take additional mathematics, physics and physical chemistry. One intending to take up practical design would find additional work relating to the materials used in his type of engineering, such as chemistry and metallurgy, very useful. The opinion is expressed that it is generally better for the young engineer to enter industry as soon as possible after completing his undergraduate course.

During the depression, the business of many industries decreased by 20–60 per cent of previous levels. The heavy industries were as a rule the most severely affected. During the lowest level, it was difficult for engineering graduates to find employment. Now industry is increasing and the prospects are good. As a rule, employers can engage their old employees with specific experience and ability, but some of these have taken up activities outside the engineering industry and so there is a demand for young engineers. In some cases the latter have a great advantage over the older men, as they know the latest theories and methods and have not forgotten how to handle the technical details in calculations, laboratory and similar work.

Mr. Hellmund has noticed that about seventy per cent of all engineering graduates express a desire to go into power transmission work, the design of large machinery, railway electrification and similar work. As they all cannot get employment in this direction, it is necessary to persuade some of them to take up other activities. The author can recall no instance where the men who took his advice afterwards regretted their action, as they soon found that there are very interesting and important problems in almost every branch of engineering. The young engineer need not fear to enter work not entirely in accord with his wishes. He should prepare himself to handle effectively the work assigned to him.

Chemistry of Fibres

THREE papers read at the annual conference of the Textile Institute held in London on June 3–6 dealt with various aspects of the chemistry of fibres.

One of these was a comprehensive summary by G. F. Davidson of current theories of the molecular structure of cellulose. After an outline of the chemical and physical evidence in support of the molecular chain theory, the membrane theory of Hess was dealt with critically; the author, in common with most other investigators, appears to prefer the former. Six methods for the determination of the molecular weight of cellulose and its derivatives were then described, and the difficulty of correlating and interpreting the resulting values was emphasized. Thus, chemical determinations of end-groups give the 'molecular weight' of the largest unit within which the atoms are bound by primary valencies; osmotic pressure and ultra-centrifuge methods measure only particle size and, therefore, depend on the degree of aggregation of the molecules; whilst viscosity measurements must be standardized against an absolute method.

The second part of the paper described how the methods devised by the British Cotton Industry Research Association for the preparation of modified cotton cellulose by the action of acids and oxidizing agents have enabled evidence in support of the chain theory to be obtained.

A second paper, entitled "Wood Pulp for the Rayon Industries", by L. Hebbs, contained some interesting side-lights on the influence of the early work of the late C. F. Cross. Thus, it was pointed out that so long ago as 1904 a pulp with an α-cellulose content of 88·8 per cent had been produced by mercerization with alkali. Moreover, in 1906 an analytical method for the determination of α-cellulose was outlined, which is essentially the same as that used to-day. The correlation of the copper number and the cuprammonium- and viscose-viscosities with the strength and cellulose purity of pulp was then discussed, the relationships being illustrated graphically. The elimination of resinous matter in the manufacture of wood pulp is greatly assisted by removal by washing and screening of the small sacs, medullary rays and short fibres in which it is concentrated, and by bleaching the pulp in several stages. Rapid replacement of cotton linters by wood pulp is expected.

In the third paper, Dr. R. Cuthill discussed the sorptive properties of the silk fibre, which are of considerable importance both from a theoretical and a practical point of view. Gases and vapours, non-electrolytes in solution and pure liquids, suspended solids, electrolytes and dyes were dealt with in turn.

Canadian Work on Dermatophyte Fungi

A NUMBER of papers by members of the University of Manitoba form an admirable review of modern knowledge of the dermatophytes, or fungi which produce ringworm and favus diseases of human skin. The general mycologist will find many features of interest in this field of specialist endeavour, and Dr. P. H. Gregory has provided adequate summaries[1].

The outstanding characteristic of a dermatophyte is that it can utilize the highly insoluble scleroprotein *keratin* as a source of energy. This is apparently accomplished by means of a keratolytic enzyme secreted by the organism. Such fungi may be introduced to unkeratinized parts of the body ; several have, indeed, been re-isolated from the blood-stream ; but they do not seem to be able to parasitize any organ but the skin.

A very high degree of specificity is found. Some species of the genus *Microsporon* produce ringworm of the scalp in children, but not in adults ; the lesions disappear naturally at puberty. Certain species parasitize the hands and feet, whilst others attack only the hairy parts of the body. *M. audouini* infects man, but not other animals. This limited pathogenicity cannot be due to chemical differences between the various sources of keratin, for a number of species will attack that substance from all sources—scalp hair from children and adults, pubic hair, human nails, porcupine quills and snake scales—when it is dissociated from living tissues.

The localized fungal infection, known as a 'mycosis', may not be the sole effect of the organism upon the host. 'Mycids' may occur. These are secondary lesions of a non-parasitic nature, but definitely associated with the presence of the fungus in another part of the body. The very great emphasis on the need for keratin as food for the parasitic dermatophytes is rather striking, as they are also saprophytes of a taste sufficiently catholic to include such diverse food substances as tinned oysters, straw, cereal grains and a wide variety of synthetic media. Their characters are also changed in the saprophytic phase, and very numerous forms of organs appear in artificial culture which are unknown in the state of natural parasitism. The spontaneous degeneration known as pleomorphism often occurs in the saprophytic phase ; but infection of animals has been accomplished from fungi which have been grown saprophytically upon keratinized tissues *in vitro* for some time. The need for investigation of natural sources of infection raises some very interesting problems for the field mycologist. From what saprophytic substrata can a dermatophyte proceed to attack a human subject ? How is the transference to the host accomplished, and by what kind of spore ?

Classification of the 880 species of dermatophytes at present described is very difficult. Four different systems of grouping have been suggested, but the general mycologist would only be at home with that of Langeron and Milochevitch, which includes all the ringworm and favus fungi in the Gymnoascaceæ, though perhaps, as yet, with insufficient justification. The system originally proposed by Sabouraud, and revised in 1929, is still the most useful to medical men. It also possesses sufficient parallels with the classification of the Fungi Imperfecti to enable it to be adapted mycologically as future researches should dictate. The local dermatophyte floras of various parts of the world are being studied, and Drs. A. M. Davidson and P. H. Gregory have published their quota[2]. The same two authors have also helped to simplify the problem of classification by their proof[3] that the so-called 'mosaic fungus', often associated with ringworm attacks, is in reality an intercellular deposit of cholesterol crystals. Dr. Gregory discusses reports of the discovery of asci in dermatophytes, and considers their possible relationships with other fungi.

Certain species of dermatophytes cause a green fluorescence to appear on infected hairs when viewed in ultra-violet light. This is due to the presence of a water-soluble substance, and the fact is used to facilitate the diagnosis of ringworm. Dr. A. M. Davidson, S. A. Boyd and C. P. Haltalin have described a very simple and convenient apparatus for this purpose[4]. The work, which is the result of co-operation between a research worker, a physician and an electrical engineer, is typical of the determined team spirit which is very obvious in the publications of the Manitoba workers on dermatophytes, and should not fail to yield results of practical value to humanity.

Educational Topics and Events

EDINBURGH.—Prof. James Ritchie, regius professor of natural history in the University of Aberdeen, has been appointed to the chair of natural history, in succession to the late Prof. J. H. Ashworth.

The degree of Doctor of Science has been conferred upon the following : A. B. Brown, for a thesis entitled : "Studies in Cambial Activity" ; Sasindra Chandra Dhar, for a thesis entitled : "On certain Investigations of the Properties of the Functions of Mathieu, Whittaker, Weber and other Confluent Hypergeometric Functions : On the Uniformization of Algebraic Curves, and on certain Electromagnetic Waves in Gravitational Fields in Relativity" ; Nancy M. Galpin, for a thesis entitled : "Biological and Statistical Studies on the New Zealand Romney Lamb, with reference to Relative Growth Gradients" ; J. M. Stagg, for papers on "Terrestrial Magnetism, with special reference to the Magnetic and Non-photographic Auroral Data brought back from Fort Rae, North-West Canada" ; J. Carmichael, for a thesis entitled : "Investigations into Tuberculosis in Uganda" ; Philippus L. le Roux, for a thesis entitled : "Observations on Schistosomiasis and Paramphistomiasis in Sheep, and Notes on the Morphology of Helminths from Mammals and Birds in South Africa".

LONDON.—Dr. W. J. Hamilton, since 1935 lecturer and deputy director of anatomy at St. Thomas's Hospital Medical School, has been appointed University professor of anatomy (St. Bartholomew's Hospital Medical College).

It has been resolved to institute a B.Sc. degree in chemical engineering for internal students in the Faculty of Engineering.

The following D.Sc. degrees have been conferred : In agriculture, on P. H. H. Gray, of the Rothamsted Experimental Station ; in botany, on W. A. Roach, a recognized teacher at the East Malling Research Station; in botany, on F. C. Steward, of Birkbeck College; in fuel technology, on R. J. Sarjant, of the Imperial College (Royal College of Science); in history, methods and principles of science, on Dr. Douglas McKie, a recognized teacher at University College; in physical chemistry, on C. F. Goodeve, a recognized teacher at University College; in zoology, on R. J. Ortlepp, of the London School of Hygiene and Tropical Medicine.

Alexander Haddow has been re-appointed to the Laura de Saliceto studentship for the year 1936–37. The Sir George Jessel studentship in mathematics for 1936 has been awarded to W. J. E. Butler, of University College.

BEIT fellowships for scientific research, tenable at the Imperial College of Science and Technology during the academic year 1936–37 have been awarded as follows: extensions of fellowships to R. Walls, for the continuation of his research on the metamorphic rocks of north-east Scotland, under the direction of Prof. P. G. H. Boswell; E. W. Hewson, for the continuation of his research in meteorology, more especially the detailed structure of discontinuities between air masses as occurring in England and Canada, under the direction of Prof. D. Brunt. New fellowships have been awarded to: E. K. Woodford, of Olds School of Agriculture, Alberta, 1929–30, and the University of Alberta, 1930–36, for research in the physiology of plants, with special reference to problems of plant growth and metabolism, under Prof. V. H. Blackman; Dr. N. Kemmer, of the Universities of Gottingen and Zurich, for mathematics research, using the ideas and formalisms of quantum theory (especially quantum electrodynamics), under Prof. S. Chapman.

A NEW handbook of information about facilities available for students from other countries at university institutions in Great Britain and Ireland has been published by the Universities Bureau of the British Empire (88a, Gower Street, London, W.C.1). In the sixty-four pages of this pamphlet are set out, succinctly but lucidly, indications of conditions of admission, costs of living, fees and other charges, courses and subjects of study, special courses for overseas students, vacation courses, social amenities, some features of university administration and notes on research facilities and open scholarships. Under the heading "Cost of Living", overseas students are strongly recommended to obtain entrance to hostels, as they provide contacts which are not readily obtainable in the seclusion of lodgings and boarding-houses or even in families where students are received as paying guests. The list of courses of study comprises those which experience has shown may be of special interest to overseas students and research workers. Among special courses for overseas students mention is made of an offer by Ashburne Hall of Residence for university women, Manchester, of places at reduced fees (£13 for the term or £1 5*s.* per week) to foreign women students prepared to give some conversational French, German, Italian or Spanish to students resident in the Hall. Other institutions which offer special courses for overseas students are: University College, London; London School of Economics and Political Science; University College, Exeter; University College, Nottingham; and University College, Southampton.

Science News a Century Ago

Progress on the Liverpool and Manchester Railway

AT a meeting of the proprietors of the Liverpool and Manchester Railway held in Liverpool on July 27, 1836, it was reported that the receipts for the half-year ending June 30, 1836, had been £109,355, and the expenses £69,953. It was also reported that the tunnel at the new station, in Lime Street, Liverpool, would be opened for public business on August 15, and that this new means of approach to the railway would prove of great public accommodation. The expense of erecting this station and the one at Edgehill, which was constructed on a most magnificent scale, amounted to about £150,000. The directors also intended, it was said, to erect a commodious station in Manchester similar to the one at Liverpool, and with that view extensive premises had been purchased in the neighbourhood of Water Street, near the River Irwell.

The Euphrates Expedition

IN a supplement to the *London Gazette* of July 29, 1836, a dispatch from Colonel Chesney to the India Office was published describing the loss of the steamer *Tigris*, the smaller of the two steam-vessels with which he was descending the Euphrates to the Persian Gulf. His dispatch was dated May 28, 1836, from the steamer *Euphrates* at Anna. All had been going well, he said, up to May 17, the survey having been carried 509 miles down the great river and "all was continued prosperity up to the afternoon of the 21st inst when it pleased God to send the calamitous event of which it is now my duty to give a feeble sketch. A little after 1 p.m. the flat boats being a little ahead, and the *Tigris* leading the *Euphrates*, a storm appeared bringing with it, high in the air, clouds of sand from the west-north-west quarter. At the moment we were passing over the rocks of Is Geria (deeply covered) and immediately after made a signal for the *Euphrates* to choose a berth and make fast. . . . The *Tigris* was immediately directed towards the bank against which she struck without injury but with so much violence as to recoil a distance of about eight yards." The wind then veered, said Col. Chesney, the water came aboard and the vessel soon sank. Col. Chesney escaped, but no fewer than twenty officers and men were drowned. The storm only lasted about 12 minutes. In spite of the disaster, which included the loss of instruments, journals and surveys, the work of the expedition was carried on by the *Euphrates* alone, "the party continuing their survey to Bussora hoping to demonstrate the speed, economy and commercial advantages of the river Euphrates".

Medicine in Denmark

ON July 30, 1836, the *London Medical Gazette* published the following note: "Every physician and surgeon in Denmark gets an education which qualifies him to maintain the dignity of his profession, as a worthy member of a class that is generally considered to be one of the most respectable and most liberal. The Danish medical men are usually held in high esteem. . . . Danish physicians and surgeons are so honoured abroad that very often Swedes come to Copenhagen in order to be treated by them. Mountebanks and quacks among the Danish medical men are rare. . . . The learning and scientific intercourse among the medical men in the Danish capital are supported by two medical societies. In their general methods of cure the Danish medical men do not commonly use but rather shun heroic remedies: as true sons of Hippocrates they follow his maxims in studying Nature and in endeavouring in all their treatment to obey it and to sustain the *vires medicatrices* not disturbing them by too active medicine".

The Siamese Twins

The British and Foreign Medical Review for July 1836 gives the following account of this interesting pair, who were then in Paris: "The connecting band united them at first face to face, but constant traction has so changed its direction that they are now side by side. Its length above is two inches, below nearly four; from above downwards it measures three inches, and its greatest thickness is one and a half inch. . . . The band is formed superiorly by the xiphoid appendix and by some of the cartilages of the ribs, and presents inferiorly the cicatrix of the umbilicus: the cavities of the two chests do not communicate, but the abdominal cavities do. . . .

It has been proposed to divide the band, but, if this description be correct, any incision would open the peritoneum; such a proposal is very disagreeable to the twins, who have often said they have never seen any single individual so happy as they are united. Their names are Eng and Chang, and they were born in May 1811 in a small village on the coast of Siam, twenty leagues from Bankok, of Chinese parents. They have the Chinese features; the internal angles of the eyes slightly drawn down, skin yellow and hair very black; they are extraordinarily alike, only Eng is a little larger and stronger, and Chang appears to rest more willingly on his brother. They are five feet in height, well proportioned and of great muscular strength; they are very agile, they walk and run rapidly, and can swim as well as a single person. Their intellectual faculties are well developed. They understand English and speak it perfectly, but they have forgotten their native tongue, which is not to be wondered at, as they never speak to each other except sometimes asking a question. They have both an equal knowledge of English. Two persons have endeavoured to converse separately with each at the same time, but both turn invariably to one speaker, and converse alone with him. They suffered from ague in America; the attack commenced at the same time in both, and the stages of the disease exactly corresponded, so that they experienced rigors, heat and sweating at the same moment. Chang also had pain in his side, during which his brother was uncomfortable, and when Chang was being bled, Eng felt indisposed.

Their taste for food, for persons and things is similar, what pleases one, pleases the other; they both experience hunger and thirst, go to sleep and wake at the same instant; one is never awake while the other sleeps, and to wake them it is only necessary to touch one. During sleep they often change their position by one rolling over the other without waking. There is the utmost uniformity in their motions, as if both were influenced by one will. They have never been known to be angry with each other; the one who wishes to perform any act, makes no sign to the other, who, notwithstanding, concurs without the slightest hesitation".

Societies and Academies

Edinburgh

Royal Society, July 6.

B. G. SHAPIRO and H. ZWARENSTEIN: Relation of the pituitary gland to muscle creatine. The creatine content of the thigh muscles of *Xenopus lævis* is about 400 mgm. per 100 gm., the extreme limits for normal animals, male or female, being 40 mgm. above or below this figure. Six months after total removal of the pituitary gland, the muscle creatine content is found to be about 320 mgm. per 100 gm. The same result follows the removal of the anterior lobe alone. The drop does not follow immediately after operation, and is still comparatively slight after three months have elapsed. Injection of anterior lobe extract into normal toads of the same species raises the muscle creatine level by thirty per cent. This effect is tissue specific.

EDITH A. T. NICOL: The fauna of the brackish water lochs of North Uist. These lochs lie at different levels and show all conditions between lochs entered by every tide with a salinity of more than thirty per mille and those entered by only the highest tides with a salinity of about two per mille. The pH varies between 7·8 and 9·9 in spite of the low pH of the fresh-water and the alkali reserve is often below 0·0010 N. The fauna is unusually rich owing to the varied conditions of salinity and substratum, and consists of 59 marine, 24 fresh- and 25 brackish-water species, as well as 5 euryhaline forms. *Sphaeroma hookeri* is recorded for the first time in Scotland.

P. C. KOLLER: The chromosomes of the male grey squirrel. The diploid chromosome number of the grey squirrel (*Sciurus carolinensis leucotus* Gapper) is 28. The sex chromosomes exhibit very little difference in size. The sex bivalent during meiotic metaphase is invariably asymmetrical, which indicates an obligatory pre-reduction. A deviation of metaphase chiasma frequencies, found in different individuals, is brought about by a different degree of terminalization of diplotene chiasmata. The ultimate cause of the deviation is either genetical or environmental.

F. WALKER and C. F. DAVIDSON: A contribution to the geology of the Faeroes. The eighteen islands of the Faeroes archipelago, 540 square miles in area, are formed of a great sequence of Tertiary basalts and tuffs, 14,000 feet thick. Small volcanic vents, sills and dykes are present, and thin seams of sediments, including lignite, are intercalated with the basalts. Traverses show that the lowest exposed horizons of the plateau, the base of which is not seen, are formed of tholeiitic basalts. These are succeeded by olivine-basalts, and in turn by a vast thickness of porphyritic feldspathic and tholeiitic basalts, capped by ankaramites and olivine-rich lavas at the highest levels. Composite flows, dyke-feeders to lavas, and other phenomena are described, and an extensive bibliography is given. Seven 'superior' chemical analyses of Faeroes rocks are now available.

F. A. E. CREW and P. C. KOLLER: Genetical and cytological studies of the intergeneric hybrid of *Cairina moschata* and *Anas platyrhyncha platyrhyncha*. The two genera are fertile *inter se*, but the hybrid is infecund. The characterization of the hybrid differs according to which way the cross is made. The male hybrid ex *Anas* (male) × *Cairina* (female) is normally equipped sexually but infecund; the female has a rudimentary ovary, infantile oviduct, exhibits no sex behaviour and in size equals the male. The male hybrid out of the reciprocal cross is infecund and much larger than the female, which has a functional ovary, an oviduct and normal sex behaviour. She lays small eggs which are infertile. The chromosome number of the two genera is probably the same and the larger chromosomes are morphologically alike. In the male hybrid no viable gametes are to be found. Spermatocytes undergo dedifferentiation and nuclear condensation. Multinucleate giant cells in which vacuoles develop and nuclei degenerate are plentiful. The spindle is normal. The sterility of the hybrid would seem to be due to the action of complementary genetic factors which do not affect chromosome pairing but which disturb the relationship of this with spindle development.

Harold Jeffreys: Note on fracture: a note on Dr. E. M. Anderson's paper "The Dynamics of the Formation of Cone-Sheets, Ring-Dykes, and Caldron-Subsidences".

Paris

Academy of Sciences, June 15 (*C.R.*, 202, 1953–2020).

Vito Volterra: The equations of biological fluctuations and the calculus of variations.

Henri Devaux: The determination of the thickness of the albumen membrane formed between water and benzene, and the properties of this membrane. The interfacial membranes of albumen between water and benzene are monomolecular.

Hugo Steinhaus: The curve of Peano and independent functions.

M. Kac: Some remarks on independent functions.

R. de Misès: The energy of acceleration of a solid.

Pierre E. Mercier: Oscillatory phenomena in suspensions.

Louis Couffignal: The use of binary numeration in calculating machines and nomomechanical instruments.

Jean Lagrula: The method of simultaneous pupillary regions. Application of Charles Fabry's method of stellate photometry. Taking four exposures on each plate, by successive rotations of a right angle, relative magnitudes have been determined with an accuracy of 0·005–0·01 magnitude.

L. Chadenson: A functional space of quantic mechanics.

Gabriel Duch: Some relations between the functions of the cohesion forces of liquids and their chemical function at the boiling point under constant pressure.

J. Serpe: The K-radiation of boron. Boron prepared by Moissan's method gives a K-radiation which has at high temperatures three conductivity electrons per atom. The maximum kinetic energy of these electrons is $20 \pm 2{\cdot}5$ v.

Jean Roig and Jean Thouvenin: The variation of the optical density of photographic plates with the dryness conditions. A photographic plate, uniformly exposed, never gives uniform darkening. One of the causes of this variation is moisture variation, and results of a quantitative study of this effect is given.

Mlle. Arlette Tournaire and Etienne Vassy: The influence of the wave-length of the light on the evolution of the latent image. The evolution of the latent image, in plates in which it occurs, is shown to be a function of the wave-length of the incident light.

René Delaplace: Atomic hydrogen and the disappearance of hydrogen in discharge tubes. If the discharge tube is freed from traces of water vapour by cooling with liquid nitrogen for twenty-four hours, the hydrogen does not undergo irreversible contraction, and traces of methane and carbon monoxide are no longer produced by prolonged discharge.

Pierre Spacu: An argento-mercuric compound. From an X-ray study it is shown that Wohler's substance $Hg(CN)_2.AgNO_3.2H_2O$ is a definite compound and not a mixture.

Etienne Canals, Max Mousseron, Louis Souche and Pierre Peyrot: The Raman spectra of some substituted epoxycyclopentanes.

Pierre Brauman: A new type of vanadylsalicylate.

Paul Couturier: The action of mixed organo-magnesium compounds on the aromatic N-diethylamides with phenolic function.

René Truchet: Heavy chloroform, $CDCl_3$. This was prepared by the action of heavy water on a suspension of quicklime in chloral, and contained only a small proportion of ordinary chloroform, shown by the Raman spectrum.

Georges Denigès: The constant formation of carbonyl derivatives (aldehydes and ketones) of the same condensation in the explosive decomposition of nitric esters.

V. Agafonoff: The soil types of Tunis.

Jean Marçais: The geological constitution of the region to the north of Taza and of Guercif (Eastern Morocco).

Maurice Roques: The cristallophyllian series of the Lespinouse massif, in the neighbourhood of Lacaune.

Waclaw Moycho: The independence of the production of proteases and the development of the cell in *Bacterium prodigiosum*. By varying either the pH or the amount of phosphate, the development of the bacterium and the production of proteases can be influenced differently. The two processes, at least in this organism, appear to be independent.

René Souèges: The embryogeny of the Campanulaceæ. The development of the embryo in *Campanula patula*.

Mlle. Marie Louise Verrier: The purple and visual cells of the fovea of the nocturnal birds and of other vertebrates.

Paul Chabanaud: The interbranchial opening of the unsymmetrical teleosteans.

Georges Brooks: Researches on the fluorescence of the skin of the frog, *Rana esculenta*. Study of the mineral substances. The mineral fluorescent substance of the skin of the frog is composed of a complex mixture of mineral salts containing manganese and zinc.

Constantin Levaditi and Perez Haber: The affinity of the virus of bird plague for the neoplasic (epithelioma) cells of mice.

Cape Town

Royal Society of South Africa, April 15.

F. G. Cawston: Some observations on *Opuntia* used as a larvicide. The mucilage of *Opuntia maxima* was tested in various concentrations, and the effect studied on four different anophelines and *Culex*. The majority of the larvæ rapidly succumbed, but the mucilage had little effect on those which had reached the pupal stage. There was also an arrest of development of those which were afterwards removed to clean water. The effect of the juice is largely mechanical, and a preservative is needed to prevent decomposition.

VIVIEN ELLENBERGER: History of the Ba-ga-Malete of Ramoutsa. The traditional and historical movements of the Malete tribe, Bechuanaland Protectorate, collected from native tribal sources and from official records. Notes on the social structure, regimental system, national praises and the tribal territory are included.

I. SCHAPERA: Acculturation among the BaKxatla.

FLORENCE RICH: Some diatoms from the Victoria Falls. An account of diatoms contained in the washings of a collection of Dicraea (Podostemaceæ) made just above the Falls, on the rocks at the east side, where these plants are covered by rapid-flowing water in the rainy season. About sixty different species have been identified, most of which proved to have been previously recorded from South or Central Africa. One new species and several new varieties are described and figured.

W. S. S. LADELL: Use of serum as an accessory medium in tissue culture.

H. ZWARENSTEIN: A revised simple technique for the frog test.

V. SCHRIRE and H. ZWARENSTEIN: The pancreas and blood inorganic phosphorus. The normal plasma inorganic phosphorus content of *Xenopus* is 7·1 mgm. per 100 ml. (average of 58 estimations). Temperature has no effect. Pancreatectomy caused a 30 per cent increase six hours after operation. Injection of insulin into normal animals caused a 50 per cent drop four hours after injection.

Cracow

Polish Academy of Science and Letters, April 6.

W. ORLICZ: The L^M spaces.

K. ŠTEINS: The technique of astronomical calculations according to an international inquiry. Some conclusions based on a questionnaire sent out to twenty-two countries relating to various points in astronomical calculations.

S. PIOTROWSKI: A star, probably new, in Gemini.

K. GUMINSKI: The luminescence of barrier anodes of aluminium. A study of the influence of the nature of the electrolyte, of the anode and the electrical conditions on the light emission of the anodes. The results are discussed from the point of view of the current theories of this luminescence.

I. ZLOTOWSKI: The structure and properties of the insulating layers formed on aluminium electrodes during anodic polarization.

K. DZIEWONSKI and J. MOSZEW: The reactions of methyl-*m*-xylyl ketone with compounds of the thiocarbanilide type.

A. KOCWA: The reactions of the alkyl-aryl-pyrazolones and their derivatives of the anil type with carbanil and thiocarbanil.

MLLE. J. BURTAN: The stratigraphy of the Silesian Beskide.

J. CUNGE: The cyto-architectonic of the cerebral cortex in Japanese waltzing mice.

T. VETULANI: The forest tarpan recently introduced into the forest of Bialowieza.

Electrical Interference with Broadcasting

ONE of the difficulties in ensuring the good reception of broadcast programmes is that many of the various electrical appliances and plant in common use emit radiation which travels to neighbouring radio receivers, and there produces a noisy disturbance mixed with the broadcasting programmes. Some three years ago, the Council of the Institution of Electrical Engineers set up a committee, representative of all sections of the electrical and radio industry, to study this problem, and to make recommendations as to the steps, if any, to be taken to secure the elimination or mitigation of electrical interference with radio reception. This committee, under the chairmanship of Mr. C. C. Paterson, has recently issued its report, copies of which are now available from the Institution of Electrical Engineers (price 6*d.* post paid).

Even before the formation of this committee, the Post Office had commenced the investigation of complaints of interference received from the general public. This work has been continued, and at the present time the appropriate staff deals with about 40,000 complaints a year. As a result of this activity, a considerable measure of radio interference correction has taken place by the voluntary application of the indicated remedies by the owners of the plant or apparatus concerned. The Post Office has no powers in this matter, however, and it has been found that in a small proportion of cases the owners of the offending apparatus refuse to do anything to remove the trouble.

The Committee has expressed the opinion that the desirable objective is defined by the statement that with the field strength of the wanted radio signal of 1 millivolt per metre, when the modulation is 80 per cent, the maximum permissible interfering field strength should be 40 decibels below this value. With this objective in view, a method of measurement has been agreed upon, and instruments have been developed which are capable of indicating with sufficient accuracy the amount of interference caused by much of the electrical apparatus creating trouble. Such apparatus comprises lifts, trolley-buses and trams, household electrical appliances, small electric motors, neon signs, rectifiers and electro-medical apparatus. While at the present time automobile and aircraft ignition systems produce no appreciable interference with broadcast reception on its present wave-lengths, it is possible that trouble may be expected from such systems if they remain uncorrected when television service begins.

During the work of the main committee, a considerable amount of investigation of the problem has been conducted by four sub-committees working in co-operation with the British Broadcasting Corporation, the Post Office, the British Electrical and Allied Industries Research Associations, the British Electrical and Allied Manufacturers Association and various supply authorities and transport undertakings. Also, in view of the necessity of catering for the interests of export trade, representation was obtained on a special international committee set up by the International Electrotechnical Commission in 1934. The British Standards Institution has also set up committees to draft various specifications for components, apparatus and measuring instruments, and these are now in course of publication.

As a result of all this work, the committee now considers it necessary to ensure that all electrical appliances should conform to these specifications and be sold as being free from interference. It therefore suggests first, that the Electricity Commissioners should be given powers to draw up regulations in respect of any apparatus or plant, new and existing, which may cause interference with radio reception; and secondly, that the Post Office should be given powers to enforce these regulations. No special difficulty is seen in applying the regulations to new apparatus, and the cost of the mitigating devices is in most cases only a small percentage of that of the appliance. In the case of appliances already in use, the question of who is to meet the cost of suppression is considered to be a matter for the legislature to decide.

The report shows that a somewhat complicated subject has been explored in a very thorough and fruitful manner by the co-operative effort of representatives of all the parties concerned, and the conclusions reached and recommendations made will, in general, be regarded as very satisfactory. It will probably be some considerable time before legislation and regulations can be made effective, and in the meantime, the Institution of Electrical Engineers appeals to the general public to continue the goodwill on which the Post Office has been enabled to build up its very successful work in suppressing interference with broadcasting.

The Medical Curriculum

AT a meeting on May 29, the General Medical Council adopted certain resolutions in regard to professional education. These will come into operation on January 1, 1938, and include the following:

In the pre-registration requirements, it is laid down that every applicant for registration as a student by the Council or for admission to the medical curriculum proper should have passed (*a*), a recognised preliminary examination in general education as laid down in the Regulations of the Council; and, in addition (*b*), an examination or examinations conducted or recognized by one of the licensing bodies.

The subjects to be included under (*b*) are:

(1) One *or* two subjects of general education, other than chemistry, physics, or biology, at a standard higher than that of the preliminary examination, for those who have received their instruction in these subjects before entering universities, university colleges, or medical schools.

(2) Chemistry (theoretical and practical), the elementary principles of general and physical chemistry, and of the chemical combination of elements, including carbon.

(3) Physics (theoretical and practical), the elementary mechanics of solids and fluids, the elements of heat, light, sound, electricity and magnetism.

The examination in biology (theoretical and practical) may be taken either before or after registration as a student.

It will be remembered that about a year ago a conference of representatives nominated by the Universities of Oxford, Cambridge and London; the Royal College of Physicians of London; the Royal College of Surgeons of England and the Society of Apothecaries of London published a report on the medical curriculum (see NATURE, July 20, 1935, p. 90, and Nov. 2, p. 706). The report stressed the need for a continuance of the general education of intending medical students of post-School Certificate stage, and therefore recommended that "the Licensing Bodies consider the possibility of allowing and encouraging exemption from the 1st M.B. examination by means of a Higher School Certificate Examination conducted by any recognised Examining Body in which, in addition to the three principal scientific subjects, a subsidiary non-scientific subject be taken".

The Higher School Certificate Examination is the normal objective of the post-School Certificate student in public and secondary schools, and if the licensing bodies would recognize for the purpose of exemption from the second examination stated in pre-registration requirements those subjects in which a student has passed a Higher School Certificate Examination (chemistry, physics, biology to 'Group' standard and non-scientific subjects to 'Subsidiary' standard), they will impart to the Higher School Certificate examination a value which has been questioned in the past by so many intending medical students. The recognition would also lead to greater uniformity in the education of post-School Certificate students in the schools, and would go a long way towards removing the evil of segregation of intending medical students from the rest of the school.

Teaching Elementary Physics

(1) College Physics

By Prof. C. E. Mendenhall, Prof. A. S. Eve and Prof. D. A. Keys. Pp. xi + 592. (Boston, New York, Chicago and London: D. C. Heath and Co., 1935.) 3·76 dollars.

(2) A Complete Physics written for London Medical Students and General Use

By W. H. White. Pp. vii + 848. (London: Richard Clay and Sons, Ltd., n.d.) 15*s.*

(3) Experimental Electricity

By M. M. Das. Pp. xvi + 334. (London: English Universities Press, Ltd., 1935.) 4*s.* 6*d.*

(4) Light and Sound

By H. G. Lambert and P. E. Andrews. (Elementary Science Series.) Pp. vii + 183. (London: University Tutorial Press, Ltd., 1935.) 2*s.* 3*d.*

(5) School Certificate Examples in Physics

By Dr. W. G. Davies. Pp. vii + 176. (London: Edward Arnold and Co., 1935.) 2*s.* 6*d.*

(6) Laboratory Manual in Physics

By Prof. A. A. Knowlton and Prof. Marcus O'Day. Second edition. Pp. xi + 137. (New York and London: McGraw-Hill Book Co., Inc., 1935.) 7*s.* 6*d.* net.

(7) Praktische Physik:

zum Gebrauch für Unterricht, Forschung und Technik. Von F. Kohlrausch. Siebzehnte vollständig neu bearbeitete Auflage. Herausgegeben von F. Henning. Pp. x + 958. (Leipzig und Berlin: B. G. Teubner, 1935.) 32 gold marks (inland); 24 gold marks (abroad).

THE present system of examinations has recently been subjected to much adverse criticism, and the possibility that good may have arisen from the system seems rarely to be considered. This system in general has led to systematic teaching, and the results of this are clear in the present standard of training in elementary physics compared with that of twenty years ago. Physics was then in many schools rather a neglected subject, whereas there is now a reasonably high general level of attainment. Of course, it is always possible to sacrifice the teaching so that passing an examination becomes its main purpose; but the examination can scarcely be held wholly responsible for this evil.

The need for systematic teaching has in turn produced the need for suitable text-books, and while most of these keep an eye on some examination, they generally contribute something to the advancement of the subject. A general need has been created for the production of books of an elementary nature calculated to help beginners in the subject. The frequent publication of new books and fresh editions indicates a lively interest in teaching the subject. The variety shown in their methods of treatment assures us that the subject will not become too standardised in character, each teacher bringing some fresh ideas to the subject as the result of his own enthusiasm. No one but an enthusiast who has at least a few new ideas to communicate is likely to embark upon the task of writing a text-book of physics. Thus each of the books now considered should in its own way add something to the teaching of the subject, and particularly to the originality of the treatment.

(1) "College Physics" by Prof. C. E. Mendenhall, Prof. A. S. Eve and Prof. D. A. Keys provides an introductory course in the subject, and its most striking feature is the logical and clear development of physical ideas throughout the work. It is surprising how much ground is safely covered in a book which is not unduly bulky. The authors rightly recognise that there can be no real distinction between 'classical' and 'modern' physics, and do not hesitate to introduce new ideas which take their place naturally with the rest. The effort which the authors have made to show that many of the basic ideas of modern theory are not essentially more difficult to follow than those of the older physics has certainly been worth while. There are interesting chapters on the constitution of matter, vibrations and waves, radio, photoelectricity, radioactivity and atomic structure, and the whole is written from a modern point of view. The readable section on thermodynamics includes an account of steam and internal combustion engines and refrigerating machines.

To cover so much ground in one book has meant the careful pruning of unessential material. The result is that the book is very pleasant and interesting to read because the development of important ideas is always kept in mind. Many students who have taken more advanced courses in physics would do well to read and master this fundamentally simple account, so as to obtain a connected view of the subject. Although it is the work of three authors, the outlook and method of treatment are very uniform. The book is attractively printed with many valuable diagrams.

This book, which tells what physics is about, is easier and more interesting to read than many popular works on the subject, so that the general reader could profit from its perusal. There seems little doubt that it will obtain a well-deserved success.

(2) "The Complete Physics" by Mr. W. H. White is essentially different in character, and has been written chiefly for the use of London medical students, frequent references being made to their examination requirements. The book covers the usual ground of an elementary text, but the many references to practical applications have been chosen to be of special interest and of value to the one class of students. Although it has clearly been written for examination purposes, nothing could be less like a typical 'cram' book on the subject. Any student who passes his examination under its friendly guidance will deserve his success. The author has tried to recapture something of the attractions of the old natural philosophy and many interesting applications show that he brings this attitude to bear on the whole subject. It is written with the unconcealed enthusiasm of an experienced teacher with a fresh and youthful outlook. The writing is in a frank and conversational style unusual in scientific text-books, and this may prove rather bewildering to the weaker students who are seeking to obtain the simple essentials of the subject. It seems likely that the book will serve those best who have already a fair elementary knowledge of physics, and it should be invaluable in enabling such students to apply their knowledge to medical purposes. Every teacher of medical students should read the book, as he cannot fail to extract much new matter from it. It brings an attitude to the subject differing greatly from that generally produced by examination requirements.

Many of the references are of a recent character and the book deals adequately with the modern developments of the subject. The author clearly recognises the dangers of his style and at the end says "maybe I have told you twice too much". Maybe he has, but much of the material is of an unusual character which cannot easily be found elsewhere. This unusual book ends with a photograph of the author at the end of the last chapter. It is a fitting way of ending a work essentially personal in character, the writing of which has clearly been a labour of love.

(3) The work of Mr. M. M. Das is suitable for students in technical colleges and secondary schools. The author makes it clear that the book has not been written with the sole object of enabling students to pass examinations; but the matter is intended to be adequate for matriculation, professional entrance, and most technical college examinations. If the book is read with the help of a teacher who will stress the fundamental principles, it should serve to excite the curiosity of the student and create enthusiasm by the variety of the practical applications of the subject. Thus there are notes on the manufacture and heat treatment of iron and steel, interesting chapters on electromagnets with practical applications, on electrolysis and its applications, and on the use and care of electrical apparatus.

It seems a pity even in an elementary book to express the units of resistivity in "ohm per cm. cube", after it has been correctly defined; but no doubt the author will think fit to change this in a later edition. The book contains rather more technical information than is generally required in a secondary school, but this would probably cause it to have added interest to many boys.

(4) The book on "Light and Sound" by Mr. H. G. Lambert and Mr. P. E. Andrews is intended as a first course for the lower science forms of public and secondary schools, and for those preparing for the general science examination of the School Certificate. It deals with the theoretical principles, and gives a series of experiments which might be performed. This suggests that it is intended for the book to be worked through systematically by both teacher and pupils. Whether any experienced teacher would be willing to submit to such restrictions in his methods is very doubtful. At such an early stage, it is inevitable that pupils will be more interested in practical cases and applications of the subject rather than in the logical presentation of general principles. If it is necessary for the pupil at this stage to have a text-book giving a clear and concise account of the subject, then this book meets the case admirably. But are such text-books really required ? The excellent and interesting scientific information now available in children's magazines seems to offer greater attractions.

As a means of summarizing and revising what has already been taught, this book would serve a very useful purpose. It would also be of value for a young teacher who is mapping out such a course of elementary lessons.

(5) Dr. W. G. Davies's book contains more than nine hundred examples including both numerical and descriptive exercises of the type usually set in School Certificate examinations. No one wil question the value of numerical exercises even in the elementary branches of the subject. Experience shows that the candidate who can work out such examples correctly has a firm grasp of the subject The experienced teacher will generally have a set of suitable exercises with which to illustrate and drive home the principles of the subject, but this book cannot fail to provide some new ideas.

Some of the questions are in the form of exercises on laboratory work, which may assist in avoiding the common fault of the student who knows al about the experimental details while failing to understand the underlying purpose. Of course if such exercises are used instead of laboratory measurements they would constitute an evil which is certainly not contemplated by Dr. Davies.

There is doubt as to what extent such a book of examples should be left in the hands of the student. Care will be required in the selection of examples by the teacher, and no student will be subjected to the lifeless drudgery of working through the whole book. Many text-books do not give suitable examples so that this book of exercises, many of which are of considerable physical interest, cannot fail with proper care to be of real service.

(6) The "Laboratory Manual in Physics" by Prof. A. A. Knowlton and Prof. Marcus O'Day provides a series of experiments suitable for a first-year university course. Every laboratory tends to have its own rather specialized apparatus which has gradually grown up with it. This constitutes a difficulty when considering the general adoption of any text-book of practical physics. The extent to which such a book would be useful to the student depends upon how far the available apparatus corresponds to that actually described. The book, however, would be of considerable assistance to any teacher arranging an elementary course.

The authors have aimed at producing more than a mere collection of experiments. They have tried to give a selection of exercises covering the more important concepts, and rightly stress the ideas involved, more than the manipulative details of the exercises.

The book covers all the ordinary branches of physics, including exercises on the balance and on electrostatics which are frequently omitted. It is well produced and pleasant to read.

(7) The publication of the seventeenth edition of Kohlrausch's "Practical Physics" is a matter of importance. The general editor, Dr. F. Henning, and his numerous collaborators have produced a new and thoroughly revised work. This book is different in character from those which we have been considering, as it can scarcely be said to deal with elementary physics. It is suitable for advanced students, and as a general reference book for those engaged upon research in either pure or technical physics. In addition to the detailed descriptions of certain experiments, it contains valuable general summaries of experimental methods and numerous recent references to original papers. Such references would be of the greatest help to those beginning a new line of investigation. The book opens with a general introduction on units and measurement, and then deals with mechanics and sound, heat, optics, electricity and magnetism, corpuscles and energy quanta, and concludes with a reasonably comprehensive series of tables. There seems no doubt that this edition will be as successful as its predecessors.

Mycoses of Man and other Mammals

Medical Mycology:
Fungous Diseases of Men and other Mammals. By Prof. Carroll William Dodge. Pp. 900. (London: Henry Kimpton, 1936.) 42*s*. net.

IN this work, for which Prof. C. W. Dodge is to be congratulated, the dermatologist will find a mine of information on the technical mycological details of the causative organisms which underlie that immense number of diseases of the skin and other regions of the body grouped under the generic term 'mycoses'. These are subdivided into sub-groups, such as the dermato-mycoses, etc.

In the opening chapter, the author gives a good description of the different elements which comprise the several types of fungi. In dealing with the physiology of fungi, the importance of the hydrogen ion concentration of the media and the action of buffers is stressed. The discussion of the exact meaning of both these terms, somewhat baffling to the average medical man, is clear and understandable.

The author takes a wide view of the different species described under the various genera. He indicates that many of the former may eventually be proved to be synonymous: nevertheless, the worker in mycology is given the benefit of all the published views of many authors to guide him in his studies without obtruding the author's personal views to the exclusion of the general knowledge of the subject.

Another prominent feature of this book is the extensive bibliography given after each section, which is particularly useful in following up research on an individual organism.

The reviewer is struck by the clear unbiased discussions concerning each type of infection: a good example is the preliminary dissertation on malassezia. After a general résumé of the accepted facts of distribution of lesions, embryology, age and sex incidence, etc., the author shows how the different varieties of malassezia attack the sebaceous glands, and exposes many fallacious schisms perpetrated by some of the less recent authors, who did not realise the importance of fungi in so many of the diseases under review. This is followed by the reference to some 1,375 articles bearing on the subject—a truly comprehensive and international bibliography.

Another section of the work of particular interest to the dermatologist is that on the Trichophytoneæ. The different clinical types are described with methods of prophylaxis. Many cultural methods are given to suit the various types of specimen and organism, and the therapeutical agents in common use are enumerated from two points of view: first, the drugs used by dermatologists in practice, and secondly the result of many inhibitant substances used *in vitro* in laboratories. These do not coincide, because of the differences of the conditions *in vivo* from those obtaining *in vitro*. This is attributed largely to differences in the pH value of the horny layer of the skin to which the lesions are confined, temperature of this layer and of the media, and the oxygen pressure present. The Trichophytoneæ are frequently carried in the blood stream, but do not develop in tissues other than the horny layer of the skin. The experiments proving this contention are well described, as are the allergic phenomena in infections with the Trichophytoneæ.

Aspergillaceæ and Actinomyceteæ are dealt with in the same complete and thorough manner.

In the reviewer's opinion, this work is a very important contribution in which an immense amount of the relevant bibliography is quoted and collected in its appropriate place to assist the student and research worker, and further it epitomizes the available modern knowledge of the subject. Apart from the botanic interest and classification, the ever-increasing appreciation of the medical profession of the importance and frequency of the incidence of these fungous infections in the human subject demands that every dermatologist should read this valuable book.

C. CRAWFORD-JONES.

Society and the Institution of Marriage

The Future of Marriage in Western Civilisation

By Dr. Edward Westermarck. Pp. xiv+281. (London: Macmillan and Co., Ltd., 1936.) 12*s*. 6*d*. net.

PROF. WESTERMARCK has applied his world-wide knowledge of the institution of marriage and his life-long experience in analysing its various forms and manifestations to the practical question of the present position and the future of marriage in modern Western civilization—a question indeed which has been much discussed of late years, but at present, momentarily perhaps, seems less insistent. He examines the question here from all sides. Its defects, real or alleged, and the suggested remedies are taken seriatim and discussed with a broad-minded tolerance befitting the impartial attitude of the man of science and the philosopher. This is a point which it is not otiose to make, as Prof. Westermarck has been accused by some of his critics of a bias which makes the monogamous marriage the touchstone of his conclusions as the ultimate and highest development of the institution—in other words, that his arguments have an ethical rather than a scientific background.

History, we are often told, repeats itself. It is interesting to note that whatever the problem under consideration, whatever the remedy which has been tried or is being discussed, Prof. Westermarck has an apposite parallel to cite from the vast store of his knowledge of primitive, barbarian or extra-European culture and from all time. Yet with all this wealth of detail at his command, no mechanical citation of parallels, as he explains in summing up his thesis, has been allowed to offer a speciously facile solution of the problem. He probes more deeply, seeking the underlying causes, that is, the emotional urges which, persistent and perennial, have moulded and will continue to mould the union of the sexes in their chief function, that is, the continuance of the species.

In other words, Prof. Westermarck believes the continued existence of the monogamous marriage as an institution, whatever subsidiary relaxations may be admitted for more aberrant or special needs, is assured as the permanent, and in the long run predominant, form of union. This depends mainly, if not completely, upon its function as the bond of the family, into which children are born and in which they are reared—this only, however, while there is no change in the fundamental urges of human nature as they have existed and persisted up to the present day.

To some it may seem that this conclusion begs the question and leaves the problem unresolved. To Prof. Westermarck, with his world-wide outlook, however, present discontents are but as transient ripples on the pool.

Foundations of Physics

By Prof. R. B. Lindsay and Prof. H. Margenau. Pp. xiv+537. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 22*s*. 6*d*. net.

THERE is a type of theoretical physics which consists in the mechanical use of mathematical apparatus; it is to be met with at all stages. The intermediate student develops a fatal facility in the handling of $1/v + 1/u = 1/f$, knowing little and caring less about the physics that is involved. Later, his theoretical physics is summed up in certain differential equations of the second order and, arrived at the boundaries of his subject, we may see him later still employing the most recent technique in matrix theory and in vector algebra, finding in this technique an instrument for saving, rather than for stimulating, thought.

The authors of this most valuable volume by no means despise mathematical aids, but mathematics is always the servant, and there is no danger of losing the physical argument in a maze of mechanically handled mathematical symbols. The book is a real study of the foundations of physics, and whether the authors are engaged in the exposition of the bases of classical mechanics, or in explaining the statistical point of view, the electron theory and special relativity, or the latest developments in quantum mechanics, they are clear, critical and stimulating.

It is not too much to say that the book is one of the best attempts that have yet been made to survey the foundations of modern physics in a manner at once thorough and yet not over-detailed. It may be unreservedly commended to the notice of students in the honours schools of physical science. A. F.

Logic in Theory and Practice

By Prof. C. G. Shaw. Pp. xvii+428. (London: Sir Isaac Pitman and Sons, Ltd., 1935.) 8*s*. 6*d*. net.

AN additional text-book of logic will not necessarily improve the "low ranking in popularity" of that subject. Yet, Prof. Shaw has written one with the object of trying to make logic "as vital and interesting as its frigid forms will permit". It is difficult to say whether the author has succeeded in this undertaking, as the response has to come from the student rather than from the teacher. But in so far as the latter is concerned, he will find little in this new book to justify its substitution for other similar works. A point in its favour is the fact that the author tries to be more human in his exposition of the traditional theories: his treatment of the logic of judgment and of the hypothetical syllogism are good illustrations of this characteristic. But on the other hand, there are many points of scientific method which he has deliberately overlooked, though they have their place in the scheme of the inductive process. The additional chapters of the theory of knowledge are not at all out of process, though they raise more problems than they can attempt to solve. The writing and the production of the book show, nevertheless, that logic still has a good following and that it deserves a still greater one. T. G.

Das Grosse Moos im westschweizerischen Seelande und die Geschichte seiner Entstehung

Von Werner Ludi. (Veröffentlichungen des Geobotanischen Institutes Rübel in Zürich, Heft 11.) Pp. 344+13 plates. (Bern: Hans Huber, 1935.) 19.80 francs.

"DAS GROSSE MOOS" is the name of the extensive plain lying between the lakes of Neuenburg (Neuchâtel), Bieler (Bienne) and Murten (Morat) in western Switzerland at the foot of the Jura range. The area has been subjected to considerable floodings, to remedy which artificial drainage on a considerable scale has been undertaken and has led to the lowering of the water-level in all the lakes and an increase in cultivated land. The volume under notice includes a very full account of the existing ecology and of the history of the area.

By a combination of methods, it is shown that there have been considerable fluctuations in water-level in the lakes, and the surrounding area, during post-glacial times. These fluctuations have been mapped mainly by the construction of pollen-diagrams, based on the examination of samples from the peat deposits, and on the correlation of the variations in pollen content with archæological and geological evidence and comparison with similar results obtained in other parts of Europe.

The work is essentially a very careful and detailed account of the influence of post-glacial climatic changes, working especially through erosion, and of man, on the topography and vegetation of a limited area in Central Europe. As such it is a valuable contribution to the accumulating knowledge of the history of European plant-life. W. B. T.

A Documentary History of Primitivism and Related Ideas

Vol. 1: Primitivism and Related Ideas in Antiquity. By Arthur O. Lovejoy and George Boas: with Supplementary Essays by W. F. Albright and P. E. Dumont. Pp. xv+482. (Baltimore: The Johns Hopkins Press; London: Oxford University Press, 1935.) 22*s*. 6*d*. net.

THIS imposing undertaking, of which the first volume is under review, proposes to give direct evidence of the views held throughout Western civilization on primitivism and related ideas. Its chief interest lies in the compilation and classification of the various quotations selected by the authors; so that it is really with a source book about the conceptions of Nature as shown through the ages that we are concerned. This first volume deals with the Greek and Roman authors, of which it gives several and large extracts. Though there is little to say about the extracts themselves, it may be pointed out that half of the labour done is of little value, for each extract is followed by a translation. The latter alone would have been sufficient.

The publication of the book, which is bound to have a limited appeal, is, however, symptomatic. For it gives an encouraging background to the advanced views about the individual and society, which are held and defended in some quarters.

The Progress of Man*

THE necessity of considering a number of controversial topics can be avoided by omitting to define the term progress, but it is generally agreed that progress, like degeneration, involves change, and while progress leads upward from a starting point, degeneration takes a downward course.

The material needs and aims of man claim first attention of a technologist. They may be grouped in a relatively small number of 'types of satisfactions'. Each of these has acquired in course of time a greater and greater variety, and a more and more involved technique of means of fulfilment, comprised in part of methods and natural materials, in part of artefacts, in varied combinations. We do not perhaps estimate the level of a culture by the nature and multiplicity of its aims; but it must be recognized that progress has depended on proliferation of aims, as much as on the multiplication of means. It might gratify our self-esteem if we could think that man's progress was determined by persistence in his aims; but this is only true of civilized communities, in which directional investigation has transformed the quest of means by inflation of the aims.

Much importance must be attached to man's attitude towards the possibility of progress in a general sense; and it is necessary to emphasize the fact that the idea is not inherent in the human mind. It is a conception of future possibilities, developed from the study of past actualities, and adopted as a framework of modern thought. We are justified in assuming that, to the early discoverers and inventors, the general idea of progress was lacking. It may be justifiably asked, however, whether the lack of a general idea of progress must be fatal to progressive steps in human culture. Since man had made great material advances long before the idea was formulated, it is clear that these were not due to perseverance in an aim that he had set before himself. As in so many spheres of human thought, theory followed practice.

That the natural environment plays an influential part in the early stages of cultural progress is obvious enough. Only in proportion as the natural environment is swamped by the artificial, does man acquire a freedom which enables him to overcome the limitations of his habitat. His success in this direction has at various periods resulted in a cultural momentum, which has taken him far from his starting point. In spite of the fact that the achievement of a high material equipment, and even a domineering empire, has often been succeeded by a crash, there has always been a continuity in many cultural elements, upon which further progress could be based. The cultivation of plants, the domestication of animals, the working of iron, and much else, once learnt, have never been forgotten, and there has, therefore, been a fluctuating continuity in human progress. But although there has been this continuity in important elements of culture, there are many instances in which its absence is conspicuous. There have been numerous false starts, numerous blind ends in human progress.

Observation and applied discoveries arise out of the opportunism that takes advantage of the accident which reveals a possibility. Here we must postulate a limited amount of foresight, leading to an adaptation or combination of known processes and methods to produce a new result. But it is the habit of the discoverer and inventor to proceed along any line that gives immediate results, and he is unable to choose the route of greatest promise. The human mind has seemed to wander without guidance—though usually in the end arriving somewhere—amongst the many possibilities of discovery and invention, striking into paths that ended blindly, returning to an old starting point, creating spurious needs and multiplying superfluities, and, in general, moving forwards, backwards, or sideways in or out of control, without knowing what its destination might turn out to be.

If material progress has been of this nature, it is clear that social progress, whether in the higher or the lower grades of culture, has had no better guidance. The customs and laws of human communities are the objective, though immaterial, products of the human mind, reacting through the ages to the stresses and strains of the environment, natural and artificial. They are comparable with the more substantial products of discovery and invention. In both, there has been an evolution, which has trespassed far beyond the biological necessities, and we are entitled to inquire whether the mind of man has been moulded in response to, and in correlation with, the exuberance of his egoistic culture. It is often said that "human nature doesn't change". Does it, or doesn't it? If it does not, can it?

The conception of the nature of human progress, here set forth, makes no allowance for an expansion of man's inherited capacity for taking pains successfully. The assumption has been made that ancient man and modern man are on the average essentially alike in potential brain-power. It might seem that the remarkable control over natural materials and forces, with the resulting creation of miracles of mechanism, is evidence that modern civilized man must be born with faculties of a higher order than those of the early representatives of *Homo sapiens*. But most of our 'miracles' are the products of the last few hundred years, and the more spectacular have emerged within the present century. In the time of Queen Elizabeth, the civilization of Europe could boast of little that was much beyond the material achievements of the old civilizations of the Near East. It can scarcely be asserted that the brain of a modern Englishman is of better quality than that of an Elizabethan. Since early times, there have been no processes of artificial selection, no eugenic measures, that can have aided in fostering types with better brains. If anything, the methods of civilization often appear to have the opposite result.

---

* Substance of the presidential address entitled "Concerning Human Progress" delivered by Dr. H. S. Harrison before the Royal Anthropological Institute on June 30.

The earliest and first type of *Homo sapiens* to appear on the spade of the archæologist is Aurignacian man, and the proposition may be argued that his physical likeness to ourselves was not accompanied by any innate and fundamental dissimilarity in brain-power. In the evolution of his material culture, man still relies upon the faculties that served his prehistoric ancestors, and if we feel less confident in making the same assumption as regards his innate moral and intellectual qualities, we need only look upon the stage of large parts of Europe and Africa to-day to realize that the experience and wisdom of millennia have failed to establish the brotherhood of man on a reciprocal basis.

If modern man, as compared with ancient man, has undergone a change of heart and mind, we are entitled to inquire by what biological compulsion this has come about. Since the human mind has determined human progress, we must consider whether those factors which are believed by some biologists to have been active in organic evolution in general can have been working on the human brain during the time that has elapsed since *Homo sapiens* first and finally became the man of modern type.

Of the various factors which have been suggested as responsible for the production of the highest type of tailless ape, natural selection, orthogenesis and use-inheritance alone concern us, as it is directional factors we seek. Yet of these it can be shown that, however much modern man may owe to natural selection for his neanthropic characters, since the directions in which it may have acted as regards man's intellectual and moral qualities are those determined by his artificial social conditions, the selection can scarcely be regarded as natural. We may admit that intra-communal selection, even in civilized societies, may foster the development of some qualities at the expense of others; but it is not evident that these qualities are such as can play a part in piloting man's progress along successful lines.

In like manner, if the increase in the size of the brain of mammals were due to an inexplicable momentum, which is imperfectly explained as orthogenesis—an inner urge towards a predetermined end—we cannot assume that the process has led, or will lead, to the production of human minds capable of distinguishing the side-tracks of moral and social progress from the highways. We cannot credit orthogenesis with the power of directing the social organism to a predetermined and desirable end.

Lastly, the factor which, if it could be shown to have been effective, would explain much of the past, and would open up a prospect for the future, namely, use-inheritance, is so strongly repudiated by most biologists that it can only have a speculative value. This is unfortunate, as an easy way to explain the origin of the modern type of man would be by acceptance of the view that both brain and hand were guided to the climax of their neanthropic powers by the summation of inherited ability, increasing through the generations. But if we accept the biological repudiation of this theory, it cannot be applied to man. In any event, we must be prepared to admit that in size and general structure the brain of man appears to have been at a standstill since early neanthropic times.

By way of provisional conclusion, it would seem that the progress of man of the species *Homo sapiens* cannot be regarded as resulting from a correlated and progressive change of heart and mind. What he was, he is, and what he is, he will be. As an opportunist, born and bred, he will go on building and re-building an environment for himself, the specifications for which are but little in advance of the construction. He knows what he is doing to-day, but to-morrow is out of sight. The mind of man has little sense of direction, and if it may be said to have an ultimate aim, that aim is too obscure for formulation. In the course of ages, man has coerced many of the forces and products of Nature to his will, but this has been a simple task compared with that upon which he is now more and more insistently engaged—the task of reconciling the fundamental weakness of his mind, and especially his power of foresight, with the social and material complexities in which he has involved himself. His hope is in himself, and not in any speculative prospect of a mental transmutation.

Low Temperatures and their Industrial Uses

IN connexion with the Very Low Temperatures Exhibition held recently at the Science Museum in South Kensington, a series of lectures was arranged, dealing both with the production of low temperatures, and with the services which low temperature work renders to technology and to pure science.

Several of the lecturers referred to the history of the successive reduction of the various gases to the liquid state, from the time when Faraday classified as 'permanent' those gases which failed to respond to his technique, up to the liquefaction of helium by Kamerlingh Onnes in 1908. Faraday's method was to compress the gas until it liquefied. Two different processes have since been used in the attainment of still lower temperatures. Both were invented in 1877, in which year they were applied to reduce oxygen to the liquid state. One process, due to Cailletet, uses the work done during expansion to liquefy the gas, whilst the other, originated by Pictet, depends on the Joule-Kelvin effect. Cailletet's method was used by Wroblewski and Olszewski in 1885 for the liquefaction of hydrogen, and was developed commercially by Claude for the production of liquid air. It has recently been modified by Simon for hydrogen and by Kapitza for helium. The alternative method, that of the Joule-Thomson effect, was used by Linde and by Hampson for the large-scale production of liquid air, by Dewar about 1896 for liquefying hydrogen in quantity and by Onnes for the liquefaction of helium, which occurs just above 4° K.

The attainment of temperatures below 1° K., that is, the passage to temperatures below that at which helium has a reasonable vapour pressure, is a very recent achievement, although the magnetic process which has since proved successful was suggested so long ago as 1923. In dealing with this subject, Dr. F. Simon pointed out that the conception of entropy as a measure of orderliness gives a simple physical explanation of the new magnetic technique, which has enabled experimenters to reach temperatures of the order of 0·01° K., and is available down to 0·001° K. Beyond this, there will be the possibility of using the nuclear paramagnetism—the magnetism due to the spin of the nuclei of atoms—and even this will not enable us to *reach* absolute zero. This, like the mathematician's infinity, cannot be attained, but can be approached as nearly as may be desired; in fact, as Dr. Simon pointed out, so long as there remain properties which vary with temperature, so long can we continue to use those same properties to reach lower temperatures.

In the domain of very low temperatures, where the vapour pressures of all known materials are quite negligible, the problem of insulating the cooled solid scarcely exists. There is no gas in which conduction or convection can occur, and radiation at these temperatures is extremely slight. So good, in fact, is the insulation, that the difficulty in the early experiments was to cool other bodies by contact with the paramagnetic salt which was used as 'refrigerant'. This is now overcome by making a pellet in which the substance to be cooled is in intimate contact with the cooling medium.

Turning now to the contributions which low temperature research has made, and is still making, to pure science, we must not overlook the fact that its contributions to industry are also contributions to pure science, for any material which is put cheaply on the market may be of value to the academic research worker.

In a more direct way, low temperature investigations are of value to the worker in pure science, in that they permit him to study the properties of matter under the condition where the heat motion of the atoms or molecules is reduced to a minimum, and where consequently these motions offer less of a masking effect to the actual inter-atomic forces. It is thus natural that low temperature work is more closely associated with atomic than with macroscopic physics. The phenomenon of supraconductivity is the example, *par excellence*, of the unexpected results attained in this field. It is now familiar knowledge that at sufficiently low temperatures, most metals lose their electrical resistance, but lately the subject has been pursued in more detail, and it has been found that the resistance is restored if a sufficient magnetic field is applied to the sample. The field necessary for the restoration increases as the temperature is lowered. This effect has, as a matter of fact, received no satisfactory explanation yet. Another case in which low temperature studies led to an advance in pure science was the discovery of krypton and xenon. This was described by Prof. M. W. Travers, who was present when Ramsay first fractionated liquid air and discovered them in it.

Prof. F. A. Lindemann, whose lecture dealt in the main with the theoretical aspects of low temperature research, pointed out that "low temperature" simply means "a temperature at which the atoms on the average contain very few quanta". It is thus in a sense accidental that the temperatures which we ordinarily think of as very low are so classified. For material in which the natural forces were of a different order, the sizes of the quanta would be different, and so the low temperature region might have been much higher or lower.

Prof. Lindemann also emphasized another important use of low temperature research. Nernst's theorem, or the third law of thermodynamics, states that entropy (that is, disorderliness, or probability of a state) decreases to zero as the temperature approaches the absolute zero of temperature. This gives us, what classical thermodynamics regarded as impossible, an absolute measure of entropy, as opposed to the measurement merely of entropy differences. Now to measure absolute entropy (from which reaction constants in chemical reactions occurring at ordinary or high temperatures can be calculated), we require measurements of the specific heats of materials right down to the point where these vanish, and hence must be able to carry out measurements at extremely low temperatures.

Since these results can be applied to such reactions as the synthetic production of ammonia and the hydrogenation of coal, they clearly impinge on the third heading under which the subject falls to be considered, namely, the practical or technological applications of low temperature research. Thus, the gases in the familiar street signs owe their commercial production to low temperature studies, and even the relatively common gas oxygen is now more frequently obtained by the fractional distillation of liquid air than by any chemical process.

The history of the commercial production of this gas, as outlined in the lecture by Mr. C. G. Bainbridge, makes a fascinating story. The barium oxide process only dates from about 1885, and, seen in the perspective of history, its duty appears to have been to build up a demand for the gas, and to stimulate the development of the associated needs, such as cylinders for its storage. It is interesting to note that the production in 1887 was about 150,000 cubic feet, and that it had risen in four years to 2 million cubic feet per annum. It is now about 8–10 million cubic feet per *week*. Its uses, too, have changed in the short period concerned. At first, it was required mainly for the lime-light, which essentially was a blowpipe, and for medical purposes. Now, the blowpipe, without the lime-light, provides one of the biggest markets, and is used in a vast variety of different industrial processes. With its aid, divers can cut steel as easily under water as it can be cut in the open air. Again, the medical or semi-medical purposes have themselves increased in number; in mine rescue work, in high altitude flying, and still more in stratosphere flights, the gas is essential, as it is in mountain climbing. (It is to be noted that all the Everest expeditions have been equipped with oxygen apparatus.) For all these purposes, the oxygen now manufactured by the liquid air process provides a cheap and easy source, and moreover, the gas so produced is actually purer than that obtained by the earlier methods. It is perhaps worthy of mention that in the factories of large users, it has now become possible to dispense with the need for transporting cylinders, which owing to their bulk and weight add appreciably to the cost of the gas. The oxygen is now distributed by pipe lines, only being evaporated at the point where it is to be utilized.

Turning from the familiar gas oxygen, we find that the fractional distillation of air yields also the so-called 'rare gases', argon, neon, helium, krypton and xenon. The last two are not in industrial use on any appreciable scale, but they have an interest here on account of the fact that they were first discovered, as Prof. Travers mentioned in his lecture, by the examination of the residues of liquid air, most of which had been allowed to evaporate. The other three rare gases were the subject of a lecture by Mr. J. T. Randall. He pointed out that helium has already been used for filling two large airships, and that it has been proposed to use the gas instead of nitrogen in the air supplied to divers. This would have the very great advantage of minimizing the danger of bubbles of gas forming in the blood when the pressure is released, since helium, unlike nitrogen, is not appreciably soluble in the blood. The most widely used gas of this group, however, is argon. Its chief use is in the gas-filled tungsten filament lamp, of which more than 1,000,000,000 are made annually. Its value here is that it lowers the tendency of the filament to evaporate, and so enables it to be run at a much higher temperature. This causes the lamp to require far less "watts per candle" than the older vacuum lamp, despite the conduction of heat through the gas to the glass envelope. The other type of lamp, the gas discharge, also relies on argon to start the discharge, although in many the vapour of mercury is the main agent for carrying the current after the discharge is started. The colours are, of course, dependent on the gas in the tube, and may be modified by the addition of luminescent solids in powder form.

All the industrial applications dealt with so far are indirect, in that the purchaser, though he may benefit from the low-temperature work, does not receive anything cold. The last example, the subject of the lecture by Dr. I. J. Faulkner, is direct. We have now become accustomed to the use of solid carbon dioxide for the refrigeration on the tricycles in which ice-cream is transported in the big towns. It has, however, many other industrial uses, and as many as 60,000–70,000 tons are now produced per annum in the United States. A surprising fact is that its loss by evaporation is quite moderate, being about 1–2 per cent by weight in 24 hours, on blocks of the ordinary size. It is also interesting to note that the gas itself, which surrounds the solid block, is a poor thermal conductor. This atmosphere of carbon dioxide is very useful when the solid material—'dry ice'—is used for the preservation of meat and fruit, since it prolongs the life of the latter, and tends to inhibit the growth of moulds and bacteria in the former case.

A growing, but less-known, use of 'dry ice' is in the machine shop, where it can be used for shrinking one part on to another, so that after the inner one warms up and expands, the joint is of enormous strength.

Solid carbon dioxide, like liquid oxygen, has removed the necessity for transporting heavy empty cylinders when supplies of the gas are required at a distance. By purchasing a block of 'dry ice', a customer with a suitable pressure vessel can obtain a supply of carbon dioxide gas from a cylinder which need never leave his premises. He simply inserts the block, closes the vessel and allows the carbon dioxide to evaporate. The gas so obtained is much purer than that from which the 'dry ice' was originally made, since the process has many of the features of the chemist's purification process of recrystallization.

Taken together, the seven lectures illustrate in a forceful manner the strides which have been made in the science and art of low temperature production and utilization, and also the interdependence of pure and applied science. The authorities of the Science Museum are to be congratulated on the provision of the course, which must have added very considerably to the interest of the Very Low Temperatures Exhibition itself, valuable though it would have been without them.

J. H. A.

Obituary

Sir William Hamer

By the death on July 7 of Sir William Heaton Hamer, at the age of seventy-four years, epidemiology has been deprived of one of its most zealous students.

William Hamer (he was knighted in 1923) was a scholar of Christ's College, Cambridge, and graduated twelfth wrangler in 1882. After graduating in medicine, he entered the Medical Department of the London County Council and rose to be Medical Officer in 1911, retiring in 1925.

Hamer's mathematical training showed itself in some of his earlier researches, particularly his elucidation of the periodicity of measles in London, which he attributed to rhythmic variation in the number of susceptibles in the population. His work on these lines was afterwards extended by the late H. E. Soper and, although it is now held that the phenomenon is not quite so simple as Hamer suggested, there is little doubt that changes in the proportion of susceptibles form an important element of the general problem.

Hamer was an acute critic of popular epidemiological theories, particularly those based upon bacteriological findings, and a sturdy champion of the doctrine of epidemic constitutions, to which he devoted years of study. The "English Hippocrates", Thomas Sydenham, propounded the general doctrine that all forms of acute diseases prevailing at the same time were linked together by common features in consequence of some general, possibly cosmic, influence which he was unable to define. Hamer attempted to bring this rather vague hypothesis into conformity with modern scientific results. It is generally agreed that, in pointing out the chronological relation of prevalences of obscure nervous diseases to pandemics of influenza, and in explaining the nature of such mysterious epidemics as the 'sweats' of the sixteenth century, Hamer made important contributions to knowledge. To most students, however, his later writings were difficult to follow, and he seemed to exaggerate the importance of Sydenham's views. At his best, he was a most stimulating writer, and he continued the scholarly tradition of Charles Creighton, linking modern science to the philosophical outlook of the ancient masters.

Mr. W. Newbold

The death, on June 24, of William Newbold, classical scholar, self-taught mathematician, statistician and biologist, at the age of fifty-eight years, just as he was within sight of retirement from his duties as an inspector of secondary schools under the Board of Education, and was wishing for leisure to extend his biological investigations, was a great shock to the large circle of friends to whom he had endeared himself by his ever-ready help and wise and kindly counsel.

Though Newbold never lost his delight in classical and archæological studies, his latent first-rate mathematical ability was, in his early manhood, stimulated by his desire to study astronomy; this led to the mastering of relativity and its application to cosmic theories; statistics next engaged his attention; and his work in this direction was invaluable to his colleagues. His eager avidity for knowledge of all kinds later drew him towards biology: here his love of observation and experimentation found its best outlet, and his work ranged over a wide field of natural history. Drawn by his combined interest in statistics and biology, he bred stick insects, to investigate their rate of increase, over a long period, keeping them in muslin meat safes, until they overflowed his study, his bedroom and his laboratory (a disused windmill). He was particularly interested in small insect parasites, especially those of birds.

The most modest and retiring of men, it never occurred to Newbold to publish any of the curious and interesting observations he made, though they were shared from time to time with his more intimate friends. A man of unusually powerful intellect, of the widest interests and sympathies, there can be no doubt that, with release from routine duties, he would have made valuable contributions to science. He met his end, which he knew for some months to be near at hand, with the utmost calm and fortitude. It is not so much as a potential man of science, but as one of far-seeing and disinterested judgment, whose wisdom in affairs was always freely at the disposal of his friends, that he will be missed.

Dr. H. J. Hansen

DR. HANS JACOB HANSEN, who died on June 26 at Gjentofte, near Copenhagen, in his eighty-first year, was one of the most distinguished of the long line of descriptive zoologists who have placed the Zoological Museum of Copenhagen in the very front rank of the museums of the world.

Hansen was born at Bellinge in the district of Odense on August 10, 1855, and studied at the University of Copenhagen, where he took the degree of Dr. phil. in 1883 with a thesis on the mouth-parts of Diptera ("Fabrica oris Dipterorum"). While still a student he worked at the Museum under J. M. C. Schiødte and in 1885 he was appointed an assistant in the entomological department, a position which he held until 1910, when in consequence of some changes in the staff he felt compelled to resign. At this time, when the continuance of his scientific work seemed to be in danger, a letter was addressed to him by a large number of zoologists in Great Britain expressing their high appreciation of his researches and their hope that he would be placed in a position to continue them. This letter was published in NATURE on March 10, 1910. Together with the efforts of his scientific friends in Denmark, this led to his being allowed to retire on full pay (although this was small enough, even by Danish standards) "for free scientific activity". He continued to work unremittingly, and letters received from him in the last year of his life were full of work in hand and plans for the future.

Except for an early contribution to the account of Danish fishes in Schiødte's "Zoologica Danica", all Hansen's published works deal with Arthropoda. Within the limits of that vast phylum, however, their range is wider than that attempted by any other zoologist of our time. Insects, Myriopoda, Crustacea, and Arachnida formed the subjects of numerous memoirs and monographs that for fullness and accuracy of detail and for exquisite illustration have never been surpassed.

Hansen's attention was especially attracted by those groups that by reason of their annectent affinities are of crucial importance to the morphologist. Thus he monographed the Arachnid Palpigradi and Podogona (until the other day among the rarest of animals) and the Myriopod Pauropoda and Symphyla; but it was on the Crustacea that the greater part of his work was done. When taking part in the first cruise of the *Ingolf* expedition to the seas of Iceland and Greenland in 1895, he devised a method of sifting the bottom deposits that revealed an astonishing variety of minute Crustacea, and he later published memoirs on the Isopoda and Tanaidacea in which large numbers of new genera and species were established, but the material of many groups still remains undescribed. Even now, little attention has been given to this micro-fauna of the sea-bottom, although it may conceivably play an important part in marine ecology.

Perhaps the most important of Hansen's contributions to morphology was a little paper on the limbs and mouth-parts of Crustacea and insects published in the *Zoologischer Anzeiger* in 1893. This was intended as preliminary to an extensive treatise on the subject which unfortunately never appeared, for when at length he published his "Studies on Arthropoda" in 1921–30, he confined himself to elaborating the details without developing further the broader views sketched in the early paper.

Apart from zoology, Hansen's interests lay mainly in politics and in military history. On these subjects he wrote much in newspapers and magazines, and he published a number of pamphlets mostly with the object of warning his countrymen against the increasing influence of German culture and German politics. He urged Danish science students to look to England rather than to Germany as their 'spiritual home', and was a caustic critic of the "Germanisering af Dansk Videnskab". Nearly all his scientific papers were published in English. In 1902 he was elected a foreign member of the Linnean Society of London.

W. T. CALMAN.

WE regret to announce the following deaths:

Sir Arnold Theiler, K.C.M.G., well known for his work in veterinary research and education in South Africa, on July 24, aged sixty-nine years.

Sir Henry Wellcome, F.R.S., governing director of the Wellcome Foundation, founder of the Wellcome Research Institution, and founder and director of the Wellcome Historical Medical Museum, on July 25, aged eighty-two years.

News and Views

Origins of Modern Races of Mankind

SIR ARTHUR KEITH's presidential address to the first Speleological Conference of the British Speleological Association held at Buxton on July 25 made a bold attempt to resolve a number of doubts and difficulties, which arise out of recent developments in the study of human palæontology. This, Sir Arthur was careful to point out, is a matter relevant to the purpose of the Conference in that discoveries of the remains of ancient types of man in caves have provided a great part of the material, which points to the necessity of recasting the current view that modern races, black, white, brown and yellow, evolved from a common mid-Pleistocene ancestral stock. It will be remembered that it has been demonstrated recently (see NATURE, 137, 73; 1936) that certain characteristics of the modern Mongolian are to be observed in the remains of Peking man found in the cave of Chou Kou Tien. Sir Arthur would go further. Not only does he too find resemblances to the Mongolian in Peking man, but he also observes Australian and Negro characteristics in *Pithecanthropus* from Java and the Kanam skull from East Africa respectively. From this evidence, therefore, he draws, somewhat tentatively, the conclusion that at the beginning of the Pleistocene, the ancestors of the Mongol, the Australian and the Negro were already in occupation of the continental areas now inhabited by their descendants; and that after their separation each race underwent a series of parallel evolutionary changes in teeth, jaws, brain and other features showing simian affinities.

IN his search for further evidence in support of his hypothesis, Sir Arthur reviewed present knowledge of early man in the areas of distribution of the main divisions of *Homo sapiens*, with the view of showing how far they exhibit traces of this parallel course of evolution. In China, unfortunately, fossil forms of man, which lead on from *Sinanthropus* towards the Chinaman of to-day, have not yet been discovered. For the evolution of the Australian type, he referred to the evidence afforded by Wadjak man from Java, with its resemblance to Talgai man, the earliest known form of Australian, and the fossil remains of Solo man, also from Java. In Africa the geological horizon of Rhodesian man is uncertain, but the Kanam fragmentary jaw from Kenya is not incompatible with the anatomy of Rhodesian man. The Kanjera skulls from deposits of mid-Pleistocene date, or earlier, are the earliest and most primitive form of Negro known to us, while in cave deposits of late Pleistocene date Dr. L. S. B. Leakey discovered fossil remains of a type still existing in north-east Africa. The gap, however, between Rhodesian man and the Kanjera negro still remains. A further problem discussed as needing solution for the acceptance of the theory was the origin of the Caucasian, who does not appear until found in late Pleistocene times as the Cromagnon man of the caves of France and other parts of Europe. For this type, Sir Arthur suggested a possible area of origin in western Asia. It is only when we accept some such view of independent, but parallel, evolution, Sir Arthur concluded, that we can give a coherent explanation of the facts known to us; but it serves only to deepen the mystery of human evolution, for it implies that the future of each race is latent in its genetic constitution. Throughout the Pleistocene period the separated branches of the human family appear to have been unfolding a programme of latent qualities inherited from a common ancestor of an earlier period.

Historical Memorial in Hatton Garden

AN interesting memorial, the institution of which was organized by Mr. E. Kilburn Scott, was unveiled at St. Andrew's Parochial School, Hatton Garden, on July 25, by the Mayor of Holborn. Much mechanical pioneering started in the district. An early connexion with engineering was in 1804, when Richard Trevithick erected his first steam-carriage in Felton's workshop in Leather Lane. Scientific instrument making began about 1750, when the Italian, F. Pastorelli, began to make thermometers, barometers, etc., the business he founded being still carried on at No. 46. In 1850 Negretti and Zambra joined in similar work, and when the Holborn Viaduct was built, removed to the present site of the Gatehouse, in which Sir Christopher Hatton resided. In 1817, P. Norton Johnson refined platinum and other rare metals in the building No. 79, where similar work is still carried on by the firm he founded. The district has long been famous for watch- and clock-making, and the name of Lund, who made chronometers at No. 4 in 1836, is still well known. St. Geo. Lane-Fox, a pioneer in the making of electric incandescent lamps, was at No. 75 in 1881, and the lamp factory at Hammersmith, built by the Brush Electrical Company to make his lamps in 1888, was eventually taken over by the General Electric Co., Ltd.

THE large building at the corner of Hatton Wall, now partly occupied by Marryat and Scott and by Raphael's, became a centre of pioneer engineering because in the basement there was a boiler and steam engine which supplied power to various tenants. One of these in 1884 was Dr. S. Z. de Ferranti, pioneer of high-tension electric transmission. Another was Sir Hiram Maxim, who developed his first automatic machine-gun in 1889, and he tried it in the basement where Hyde, the engineer, had his power plant. C. F. Cross and E. Bevan, inventors of the viscose process for making rayon fibres from sulphite wood pulp, demonstrated their process in the same building. In the early 'nineties Mr. R. W. Paul, maker of electrical instruments at No. 44, was asked to make kinetoscopes like those of Edison. In 1895 he made a projector to show the moving pictures on a screen at about the same time that Lumière was showing his in Paris. He gave his first public exhibition in the lecture room of the Finsbury Technical College, where he had formerly been a student. Hatton Garden is associated with Michael Faraday in that he had business relations with Johnson and Matthey of No. 79. Edward Barnard, of the firm occupying No. 54 (the old Court House), was father of Sarah Barnard who married Faraday. Miss Alice Faraday married Fred Barnard, grandson of Ed. Barnard, and a well-known illustrator of Dickens. For a century the district has been famous for skilled craftsmen, makers of optical apparatus, clocks and also of jewellery, etc., including pearls and diamonds. It is now the world centre for the diamond trade.

Russian Eclipse Measurements on the Ionosphere

WE have received some preliminary results from Prof. W. Kessenich, of Tomsk, U.S.S.R., of the measurements made there on the ionosphere during the total eclipse of June 19, 1936, at the suggestion of Prof. Bonch-Bruevich, and as part of the general scientific eclipse programme of the Russian Academy of Sciences. The main radio work was directed towards the solution of the problem of the source of the ionization of the F_2-layer, since earlier eclipses have indicated that the E and F_1 layers are mainly ionized by ultra-violet light. The daily variations in the critical frequencies of the ordinary (f_o) and extraordinary (f_x) rays for the F_2 layer were measured, by the pulse method, from June 16 until June 24: in addition, qualitative measurements were made, at a constant frequency, on the absorption changes during the eclipse. The receiving apparatus was in the same room as the transmitter, and included two cathode ray oscillographs, one for visual observation and the other for recording: this arrangement enabled critical frequencies to be measured in one or two minutes with an accuracy of 1 or 2 per cent. The interpretation of the results is unfortunately somewhat limited by the fact that a world-wide magnetic disturbance set in at about three hours before optical totality: this seems in no way connected with the eclipse.

THE observations were made near Tomsk, at a place about 5 km. north of the central line of the optical eclipse, and 4° south of the centre of the corpuscular eclipse (the corpuscular track, for three corpuscular speeds, 800, 1600 and 3200 km./sec., had previously been calculated by A. Michailov). The average critical-frequencies observed during the six days were much larger than those for preceding years observed elsewhere; this may be attributed to the influence of the sunspot cycle. The observations show a marked decrease in ionization of the F_2 layer during the optical eclipse, suggesting that ultra-violet light is an important part of the source of the ionization; the time of recombination seems to be of the order five minutes, agreeing with the quick appearance and disappearance of absorption at sunrise and sunset observed on preceding and following days. The occurrence of minimum ionization somewhat before totality is regarded as clearly demonstrating the temperature effects suggested by Appleton and Naismith. As regards corpuscular influence, the results are interpreted as indicating that solar particles with velocities of the order 1000–2000 km./sec. play an important part in ionizing the F_2 layer, while corpuscles of larger speed are without influence. The stronger eclipse effects observed on June 19, as compared with those found during preceding eclipses, can be ascribed partly to the summer conditions and partly to the increased solar activity in 1936. Taking into account this increased solar activity, and the high level of critical frequencies, which decreased markedly 2½ hours before totality, Prof. Kessenich and his collaborators Baerwald, Bulatov and Denisov are inclined to regard the corpuscular ionizing influences on the F_2 layer as established.

Sale of Newtoniana

As a result of the sale of the Newton Papers, and other articles of interest in connexion with Sir Isaac Newton, by Messrs. Sotheby and Co. on July 13–14, two gifts of scientific importance have now been made possible, and are worthy of record. That portion of the Papers which deal with Newton's work as warden, and afterwards master, of the Royal Mint, is bound in three folio volumes and contains 529 pieces. These were sold for £1,400 to Mr. Gabriel Wells who placed them at the disposal of Lord Wakefield at cost, on the understanding that they would be presented to the nation. Lord Wakefield has presented them to the Royal Mint, where they will be available for inspection. The very valuable and unique collection of Newtoniana already in the possession of the Royal Society has been enhanced by a gift from Sir Robert Hadfield which he purchased at the same sale. The gift comprises the following letters: four from Edmund Halley to Newton: four from Edmund Halley to Thomas Molyneux; two from Fontenelle to Newton; one from Philip Naudé to Newton; and one from Brook Taylor to Newton. A portrait of Sir Isaac Newton, painted in 1702 by Sir Godfrey Kneller (the most famous of the Newton portraits), has been purchased by the Trustees of the National Portrait Gallery (with a contribution of half from the National Art-Collections Fund) from Messrs. Rosenbach, of New York. The portrait was actually sold at the same sale for £800, but through the generosity of Dr. Philip Rosenbach, was re-sold to the Trustees of the Gallery at cost price.. Among the many other items of interest in connexion with Newton disposed of at the sale were the following: nine letters to Newton from Edmund Halley, containing the history of the publication of the "Principia" (£310); a note-book in Newton's own handwriting, giving an interesting and amusing list of expenses, and, at the other end, various problems in geometry and conic sections (£180); an autographed draft of about 1,000 words of a very important statement on the invention of the calculus (£210).

Presentation to M. Marcellin Boule

THE forthcoming retirement of the veteran anthropologist, M. Marcellin Boule, director of the Institut de Paléontologie humaine and professor of palæontology, after fifty years' service in the National Museum of Natural History, Paris, will be marked by the presentation to him of a medal by his friends and pupils as a token of admiration, gratitude and affection. M. Boule has long been recognized not merely as the leading authority in France on early man, but also as one of the very select few among anthropologists at large whose verdict on any matter under argument in prehistoric archæology and human palæontology comes as near finality as is possible in that ever-expanding field of science. Of his numerous contributions to the literature of his subject, "Les Hommes Fossiles" is as widely known as it is authoritative; it will always stand as a record of conclusions based upon profound knowledge and painstaking research. The arrangements for the proposed honour to this distinguished man of science have been in the hands of a committee of which the Abbé Breuil, P. Teilhard de Chardin, Prof. Verneau and other distinguished French anthropologists are members, and on which Great Britain is represented by Sir Arthur Smith Woodward and Prof. W. J. Sollas, Belgium by Prof. C. Fraipont, Holland by Dr. É. Dubois, and Switzerland by Prof. É. Pittard. A replica in bronze of the medal, which is the work of A. de Jaeger, will be presented to each subscriber to the fund, of which the secretaries are MM. J. Cottreau, J. Piveteau, H. Vallois and R. Vaufrey; treasurer, M. Georges Masson. The minimum amount of a contribution is 100 francs; and it should be addressed, 120 boulevard Saint-Germain, Paris (vi^e).

Recent Acquisitions at the British Museum (Natural History)

THE Department of Zoology has received as a permanent loan from His Majesty the King a mounted specimen of a cock scarlet-breasted parrakeet (*Neophema splendida*) which was formerly kept as a pet by His late Majesty King George V. This beautifully coloured bird, together with six other members of the same genus, is a native of Australia; it is now very rare, and the Museum possesses only a few examples. Two important collections have been acquired by the Department of Geology. One comprises a large series of Pleistocene and Quaternary mammals, chiefly from Clacton and the Lee Valley, collected over a series of many years by Mr. S. Hazzledine Warren, of Loughton, with special regard to their exact horizon and locality. The other acquisition consists of nearly two hundred type and figured specimens from the collection of Mr. J. W. Tutcher, of Bristol, of Jurassic invertebrate fossils, mostly Liassic ammonites from the Radstock district, described by the late Mr. S. S. Buckman. Mr. F. N. Ashcroft, who has long been a generous donor to the Mineral Department, has presented a further selection from his collection of Swiss minerals. The selection numbers about eighty-four specimens from twenty carefully recorded localities, and forms a valuable addition to the now extensive series of specimens from Switzerland in the Collection. The recent cliff fall between Newton and Yarmouth brought to light the existence in the Isle of Wight of gypsum. Mr. W. White has given the Museum one of the largest crystals that has been found. The most conspicuous of the purchases are a group of well-formed crystals of the beautiful emerald-green copper mineral, dioptase, from the French Congo, a magnificent group of prismatic crystals of celestine, and a large well-crystallized specimen of native copper.

Prices of Biological Books in 1935

THIS analysis of the cost of biological books in 1935 by John R. Miner (*Quart. Rev. Biol.*, Dec. 1935) is the tenth of its kind, and allows of a comparison between the current prices and those of 1926, as well as between those of 1934 and 1935. The prices are quoted in cents per page and at the current rate of exchange into United States currency. The number of pages reviewed is 143,199, an increase of 15·6 per cent over 1934 and 73·4 per cent over 1926. The cheapest of all publications are those of the U.S. Government, which are only 0·11 cents per page, a truly astounding figure which represents a reduction of 38·9 per cent on 1934 and 64·5 per cent on 1926. The next cheapest are those of the British Government at 0·50 cents per page, a decrease of 43·8 per cent from 1934. It is pointed out that there has been a reduction of 25 per cent in the export price of German publications which, as it occurred late in 1935, does not come into the calculations. Against this is to be set the fact that from 1934 to 1935 there has been an increase of 7·9 per cent. Moreover, over the ten years there has been an increase of 87·2 per cent in the price of these works, so that Germany heads the list with an absolute price of 2·04 cents per page, or nearly twenty times that of the U.S. Government or two and a half times that of British non-Governmental publications. France started the decennium with the low price of 0·35 cents per page, and in spite of a drop of 14 per cent from 1934 has a total increase over the period of 145·7 per cent. The non-Governmental publications of Britain are 0·84 cents per page, of France 0·86 cents per page and of the United States 0·90 cents per page. In considering these statistics, it is to be borne in mind that they are not based upon the whole of the biological books published by the countries chosen but upon such samples as passed through the hands of the reviewer. They are not absolute, therefore, but they may be taken as giving some approximation to the actual conditions.

National and International Health and Welfare

VOLUNTARY associations providing maternity and child welfare services, under the Local Government Act, 1929, now receive annual contributions from the county or county borough council in whose area or for whose benefit they work. The Minister of Health has accordingly issued a circular (1538) reminding county and county borough councils outside London that they must prepare schemes in order to secure the payment of annual contributions towards the expenses of such voluntary associations within their areas, copies of model schemes for their use being enclosed with the Circular. Respecting venereal diseases, the Minister of Health has issued circulars (1536 and 1536*a*) to the responsible port and local authorities in England and Wales enclosing a revised list of treatment centres in the chief sea and river ports throughout the world at which seamen can obtain gratuitous treatment for these diseases, in accordance with arrangements contemplated by the international agreement signed at Brussels in 1924.

The Lister Institute of Preventive Medicine

THE Annual General Meeting of this Institute was held on June 9, and the Governing Body presented the forty-second Annual Report, in which the activities of the Institute are surveyed. Investigations have been carried out upon vaccinia, tumour-exciting, neurotropic and other virus agents by the director, Prof. J. C. G. Ledingham, and Dr. E. W. Hurst, Dr. C. R. Amies and others. Various serological studies are being continued by Dr. A. Felix and collaborators. Dr. V. Korenchevsky is continuing his work on sexual hormones, and Prof. R. Robison with others is studying phosphate metabolism and tissue calcification. Investigations on rheumatism and the possible presence of a virus agent in this disease are being pursued by Dr. Amies and colleagues in conjunction with King's College Hospital. In the Division of Nutrition, much work upon vitamins and dietary constituents has been carried out by Dr. Harriette Chick and her associates. The Svedberg ultra-centrifuge, referred to in last year's Report, with accessory equipment is now in course of installation. At the Serum Department at Elstree, under Dr. G. F. Petrie, to which the Vaccine Department has now been transferred, work on meningococcus and gas-gangrene anti-sera and on staphylococcus toxin is in progress. This brief and incomplete survey illustrates the important research work now being carried on at the Lister Institute.

Experimental Research and Disease

THE tenth Stephen Paget Memorial Lecture was delivered by Sir Malcolm Watson at the annual general meeting of the Research Defence Society, held at the London School of Hygiene and Tropical Medicine on June 9, the president, Lord Lamington, occupying the chair (The *Fight against Disease*, 24, No. 3, 1936). In order to illustrate the importance of experimental research, Sir Malcolm surveyed the work of Manson upon elephantiasis and filarial periodicity and malaria, of Ross upon malaria and its transmission by mosquitoes, and of Reed upon yellow fever. By applying the knowledge won by Walter Reed and his American colleagues, the city of Havana was within a few months freed from yellow fever for the first time in a hundred and fifty years by exterminating the mosquitoes that convey the disease. Owing to an increase in member's and life-member's subscriptions for 1935, the Research Defence Society has commenced the current year with a small balance in hand.

A New Anthropological Publication

A NEW publication of the Section of Anthropology of the Department of the Social Sciences of Yale University, entitled "Yale University Publications in Anthropology", has appeared, which will embody the results of researches in the general field of anthropology directly conducted or otherwise sponsored by this Department of the Graduate School, the Department of Anthropology of the Peabody Museum, and the Department of Anthropology of the Institute of Human Relations (Yale University Press, New Haven, Conn.; London:- Oxford University Press). The issues, which will range from brief papers to extensive monographs, will be numbered consecutively as independent contributions, and will appear at irregular intervals. The first issue (Nos. 1–7) includes a study of population changes among the northern Plains Indians by Dr. Clark Wissler, an examination of regional diversity in sorcery in Polynesia by Dr. P. H. Buck, an account of cultural relations of the Gila River and Lower Colorado tribes by Dr. Leslie Spier, with several other communications dealing with aspects of the culture of the Indians of North America. A further issue of the publication, which will comprise six communications, is in the press. In view of the wide-spread activities in anthropological research of the institutions interested in this publication, and more especially of Yale University, the facilities which it will afford for early publication of results will be of great advantage to anthropologists. In this connexion, it may not be out of place to refer to the announcement that Dr. David G. Mandelbaum of Yale, who has hitherto specialized in the culture of the North American tribes, will be engaged during the coming year in an investigation among the hill tribes of Southern India.

History of Fire-Fighting in America

IN a paper received from the Smithsonian Institution, a brief history is given of fire-fighting in America from colonial days to the present time. It starts with the days of the 'bucket brigades'. Many of the earliest American communities required property owners to have fire buckets in their houses, which they had to throw into the street when a fire alarm was sounded. They were then picked up by the men who raced to the fire, and when the fire was extinguished these buckets were piled up on the village common, where the owners came to claim them. In an exhibition being held in the National Museum in Washington, many of these buckets are shown. They are made of leather, and in addition to the names of the owners are decorated with family devices and scenes of the time. The first hand-pumped fire engine or tub, made in 1740, is on exhibition; but the bucket brigades were still necessary in order to fill it with water. These tubs were pulled by hand, and at night runners went before them carrying torches or lanterns on sticks to light the way. Rival companies raced to a fire, and it was a sporting event which of them should be first there. Many incentives were offered to the companies, who sometimes did what they could to slow up their rivals. Cast iron plates were fixed to houses insured by those insurance companies paying bounties to fire-fighters who saved insured property. The fire-fighters were in great demand for parades and political rallies, and no celebration was complete without them. Next came the days of steam fire-engines pulled by horses, and then the motor fire-engine.

The Blue Water of Crater Lake

In the Cascade Mountains, Oregon, is the remarkable Crater Lake. It is about six miles long by four miles wide and lies within a volcanic crater the cliffs of which are 500–2,000 ft. high. Its depth in places is nearly 2,000 ft. It has no visible outlet, yet its water is fresh and is said never to freeze, although the surface is about 6,000 ft. above sea-level. It was discovered by white men in 1853, and was called the Deep Blue Lake. Seen from the rim of the crater, the water shades from turquoise blue along the shallow borders to darkest prussian blue in the deeper parts. From a boat, the colour deepens to dark indigo. Cloud shadows and wind flurries produce great variety in the appearance of the surface, but the main sensation produced in the eye of the observer is one of "unbelievable blueness". Dr. Edison Pettit, working on behalf of the National Academy of Sciences and the National Park Services, has recently completed a study of the reason for this extraordinary depth of blue (*News Service Bulletin* (School Edition); Carnegie Institution of Washington, 4, No. 4). He finds that the water has no special colour of its own, but that it is exceptionally free from suspended matter; such scattering of light as occurs in its depths is mainly from the water molecules, and is therefore deep blue. The degree of clarity is almost that of specially prepared dust-free water. The scattered light from dust-free water is blue at all angles; that from Crater Lake water is white only for a comparatively narrow forward angle, and at all other angles is blue.

Wooden Pipe Lines

The use of wooden pipes as a means of conveying water dates back almost to prehistoric times. They were much used in the Middle Ages. During recent years, traces of the water supply system of London (c. 1600) by means of hollow trunks of trees have often been found during excavations. In *World Power* of May, there is a paper by T. Pausert, telling how wooden pipes made of staves and bound with hoops are coming into modern practice all over the world. Generally, the staves are made of pine or larch wood, and are planed off to give a smooth finish after assembly. The contact surfaces are dove-tailed. When the pipe is filled with water, the wood swells and becomes water-tight. These wooden pipes are either placed on the ground or laid in the open on supports. Their diameters vary from 5 cm. to 6 metres. A great advantage is the immunity of the wood from the effects of water whether it is pure, acid, alkaline, saline or contains selinite. For this reason, wooden pipes are much used in the chemical industry. An important point is that salts are not deposited on the walls of the pipes, so that the latter do not become choked and their rate of flow affected. There is no risk of electrolysis from stray electric currents. If an increased pressure becomes necessary, it is easy to reinforce them by the addition of new steel hoops. If a sudden hydraulic surge occurs, the inherent elasticity acts as a safety valve; the staves being bound by hoops enable the longitudinal joints to let water escape in small jets. When the pressure comes back to normal, the staves resume their original position, and become water-tight again. Their cheapness, durability and the ease with which they can be transported in mountainous regions enable the power engineer to arrive at solutions to many of his problems by their use.

Safety on the Roads

The National Safety Congress was held in London on May 20–22. An account of the congress is given in *Roads and Road Construction* of June 1. At the Congress dinner, Sir Herbert Blain pointed out how much the British have learnt from the Americans in connexion with improving our roads and making them safer. In particular, he mentioned the practice of coloured traffic lights and of one-way streets. Although there is a magnificent system of roadways in Great Britain, there are no roads that can compare with some of the roads now being laid in America. These national highways are very wide and have a beautiful surface, good elevation and proper lighting. The curves are properly rounded, and there is no ribbon development. Mr. A. Matheson, the assistant secretary to the Minister of Transport, read a paper on "Danger Spots". Experiments have been carried out in London, where certain roads with black records have been selected. A study of these records showed that a large fraction of the accidents occurred to pedal cyclists and pedestrians. These roads were then inspected and improvements suggested which it is hoped will diminish the number of accidents. In two of the roads where the work recommended has been completed, a record was kept for six months.

In the Chiswick High Road, the number of accidents as compared with the corresponding six months of the preceding year was reduced by 37 per cent, and in the Fulham Palace Road to Putney Bridge the reduction has been from 88 to 48, or nearly 45 per cent. The Oxford County Council, becoming alarmed at the large number of accidents on its roads, made a detailed investigation of them over two years ending July 1934. The investigation showed that nearly one half of the fatal accidents occurred on certain main roads constituting less than six per cent of the total mileage of the county. During the first seventeen weeks after making certain improvements, it was found that, compared with the corresponding seventeen weeks of the preceding year, the fatalities were reduced 52 per cent and the number of injured 11·6 per cent. In Glasgow it was found that the installation of light signals at certain junctions reduced the number of accidents by about 75 per cent.

Farmer's Guide to Agricultural Research

FOR the past ten years, the Royal Agricultural Society of England has issued annual summaries of research work carried out in the leading branches in agriculture. The publication, known as the "Farmer's Guide to Agricultural Research", is now issued as a section of the Society's *Journal*, so that it may be automatically in the hands of all members. A few copies are published separately for private circulation, and a limited number of copies of previous issues (1925–33) are still available. The Society has now published its *Journal* for 1935 (vol. 96). The various sections of the Farmer's Guide are similar to those of the previous year, as are also the authors responsible for them. The remainder of the *Journal* consists of a number of special articles of outstanding interest, reports of the research work carried out under the ægis of the Society, together with a number of official reports. The volume may be obtained from the headquarters of the Society, 16 Bedford Square, London, W.C.1 (price 15*s*.).

"Index Generalis"

THE editor of the "Index Generalis", the 1936 issue of which was noticed in NATURE of July 18 (p. 100), asks us to state that new items for inclusion in this reference work are welcomed. They should be in the form in which they are to appear in print, and should be sent to Prof. R. de Montessus de Ballore, directeur de l'Index Generalis, Sorbonne, Paris V^e. No charge is made for insertions, and there is no obligation to purchase the volume. The only stipulations are that the information should be up to date and that it be revised annually on the request of the editor.

Announcements

MR. R. COPPOCK, general secretary of the National Federation of Building Trades Operatives, Mr. Richard K. Law, M.P., and Prof. B. A. McSwiney have been appointed members of the Industrial Health Research Board of the Medical Research Council.

PROF. A. MAIGE, professor of botany in the University of Lille, has been elected *Correspondant* of the Section of Botany of the Paris Academy of Sciences, in succession to the late Prof. H. Jumelle, professor of botany in the University of Marseilles.

THE Trustees of the Busk studentship in aeronautics, founded in memory of Edward Teshmaker Busk, who lost his life in 1914 while flying an experimental aeroplane, have awarded the studentship for the year 1936–7 to Mr. J. W. E. Clarke, Glasgow.

PROF. PAUL UHLENHUTH, director of the Institute of Hygiene at Freiburg i.B., has been nominated a foreign member of the Royal Academy of Sciences of Stockholm in recognition of his outstanding contributions to hygiene and bacteriology.

THE twenty-eighth annual Autumn Meeting of the Institute of Metals will be held in Paris on September 14–18. The fifteenth Autumn Lecture will be delivered in the Grande Salle, Maison de la Chimie on September 14, at 8 p.m., by Prof. P. A. J. Chevenard, who will speak on "The Scientific Organization of Factories". Further information can be obtained from the Secretary, Institute of Metals, 36 Victoria Street, London, S.W.1.

A PROVISIONAL programme has been issued of a General Discussion of the Faraday Society to be held in the Chemistry Theatre, University of Edinburgh, on September 24–26 on "Structure and Molecular Forces in (*a*) Pure Liquids and (*b*) Solutions". The scope of the meeting does not extend to kinetics, which will form the subject of a forthcoming meeting, or to subjects which have been dealt with at recent meetings, such as dipole moments and the theory of strong electrolytes. A general introduction is promised by Prof. J. Kendall. The introductory paper in Section A (Pure Liquids) will be by Prof. F. London (Oxford), and that in Section B (Solutions) by Prof. J. H. Hildebrand (Berkeley, California). As is usual in these discussions, a number of foreign guests have been invited to take part. Particulars of the meeting can be obtained from the Secretary, Faraday Society, 13 South Square, Gray's Inn, London, W.C.1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

An assistant for abstracting, indexing and proofreading in the Imperial Bureau of Animal Nutrition, Rowett Research Institute, Aberdeen—The Deputy Director (August 3).

An assistant lecturer and demonstrator in physics in the University of Leeds—The Registrar (August 10).

A lecturer in physiology (Grade II) in the University of Bristol—The Registrar (August 12).

A general inspector of education and research, agricultural and horticultural division of the Ministry of Agriculture and Fisheries—The Secretary, Minister of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (August 12).

A professor of physics (August 31) and an assistant in bacteriology (August 20) in the University of Cape Town—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, London, W.C.2.

Structural engineering assistants for the Designs Branch of the Directorate of Fortifications and Works—The Under-Secretary of State (C. 5), The War Office, London, S.W.1.

A physicist or applied mathematician to the British Cotton Industry Research Association—The Director, Shirley Institute, Didsbury, Manchester.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 207.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Preliminary Note on a New Fossil Human Skull from Swanscombe, Kent

IN June 1935, a fossilized human occipital bone was found *in situ* at a depth of 24 ft. below the surface, in the middle gravels of the Thames 100-ft. terrace at Swanscombe, Kent, in association with implements of the Acheulean culture phase. A note on the discovery appeared in NATURE of October 19, 1935, p. 637.

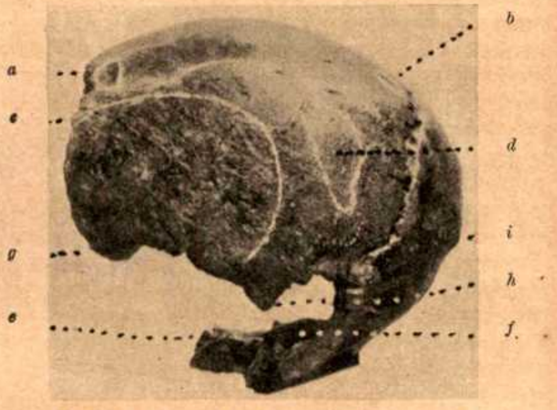

FIG. 1. Left lateral view of the Swanscombe skull.

a, Anterior oval depression.
b, Posterior round depression.
c, Temporal line.
d, Muscle attachment above and behind temporal line, perhaps for origin of functional ear muscle.
e, Basilar process.
f, Foramen magnum, filled with plasticene to support skull.
g, Inverted antero-inferior angle of parietal bone.
h, Everted postero-inferior angle.
i, External occipital protuberance.

In March 1936, at the same depth, and in the same seam of gravel, the left parietal bone of the same skull was discovered, and this was witnessed and photographed while still embedded in the gravels, by an independent observer.

Both of the bones are in a remarkable state of preservation. The occipital bone is unique among the earlier specimens of fossil man in preserving the basilar process, the foramen magnum and the condyles, and both bones are complete in all their margins. They thus furnish the important positions for cranial measurements of the bregma, lambda, asterion, opisthion, inion, pterion and basion, and the completeness of the two bones permits of the most precise measurements being taken without resort to speculation.

In its relation to other fossil types, the Swanscombe skull is to be regarded definitely as a precursor of the Piltdown type. The comparison of the Swanscombe and the Piltdown skulls may be summarized as follows.

(1) The anatomical features of the two skulls points to a definitely more primitive status for the Swanscombe skull than for Piltdown. The features of the Swanscombe are those of a specialized type less advanced than Piltdown but of the same general type, rather than a variant due to either the difference in sex or in age between two individuals of the same contemporaneous type. Both skulls are almost brachycephalic.

The main features in which the Swanscombe shows greater primitiveness are :

(*a*) Lower vault measured by the bregma-opisthion chord. Swanscombe is smaller than the lowest of the three British reconstructions of Piltdown (after Sir Grafton Elliot Smith).

(*b*) Flat ruggedness and non-filled out contours.

(*c*) Lower height and greater outward and downward slope of the parietal vault.

(*d*) The parietal eminence is not developed to the upward and backward position of Piltdown, but occupies the centre of the parietal bone.

(*e*) Lower frontal development at the coronal suture, with greater incurvature of the antero-inferior parietal angle.

(*f*) The parietal bone covers more of the frontal and the temporal regions of the brain than in Piltdown.

(*g*) An extensive obelion depression marks the sagittal border, and two peculiar depressions or pits, an anterior pit above the temporal line near the anterior border, and a posterior pit near the postero-superior angle are present.

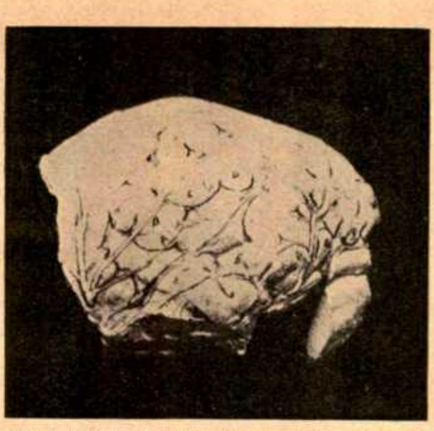

FIG. 2. Left lateral view of Swanscombe endocranial cast.

(2) The comparison of the endocranial casts of the two skulls shows a definitely more primitive stage for Swanscombe than for Piltdown.

(*a*) The visual territories on the occipital region extend over the greater part of the cerebral hemispheres covered by the occipital bone. On the left side, the sulcus lunatus crosses the line of the lambdoid suture.

(*b*) In the parietal region, the orbital, fronto-parietal and temporal opercula have not approximated at the anterior end of the horizontal limb of the fissure of Sylvius, and a large fossa lateralis measuring about 2·5 cm. from above downwards, and 1·0–2·0 cm. from before backwards is present.

(*c*) The parietal lobule, and the temporal lobe stand out in high relief as exuberant masses of neopallial growth, and the central and the intraparietal sulci occur in primitive form.

(*d*) The Sylvian fissure runs obliquely upwards and backwards.

(*e*) Low development of the parietal association area.

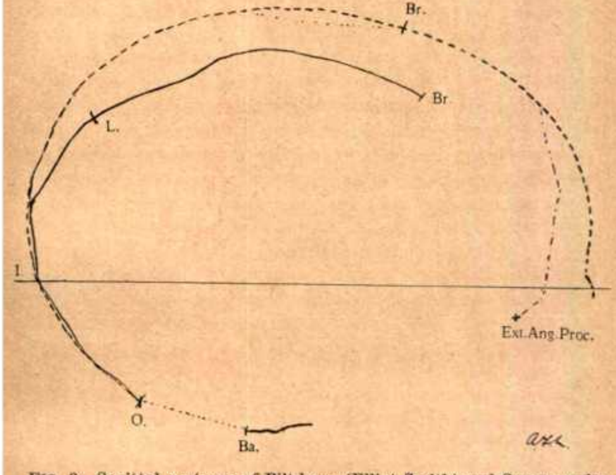

FIG. 3. Sagittal contours of Piltdown (Elliot Smith) and Swanscombe superimposed so that the inion and opisthion coincide. The Piltdown basion does not exist, but the opisthion is represented on the occipital fragment. The difference between the bregma-opisthion chord of the two specimens is not the result of the faulty reconstruction of the Piltdown skull, for if the bones of the two skulls be examined and angulated separately apart from the skull restorations as a whole, the Piltdown bones show an advanced developmental stage over the Swanscombe bones. (Swanscombe : full line. Piltdown: interrupted line.)

(*f*) The distribution of the middle meningeal arteries on the endocranial cast is more primitive in form than Piltdown.

(*g*) The shallow depth from above downwards of the cerebellar fossae is more primitive in form in Swanscombe.

Consideration of the above is sufficient to invite an inquiry into the status of the Piltdown skull. While the geological horizon of Swanscombe as the fossil of the middle gravels of the 100-ft. terrace is authenticated and recognized by the Geological Survey, the Piltdown horizon has been referred to the 80-ft. terrace, the 50-ft. terrace, and the 100-ft. terrace. The presence of the 'eoliths' or of the 'bone implement' is not reliable evidence of a Pliocene or Early Pleistocene status for Piltdown. The acquisition of a brain is a process of slow growth, and the differences between the actual anatomical features of the two skulls overwhelmingly favours the view that the geological horizon of Piltdown should be considered as later than that of the Swanscombe horizon in the middle gravels of the 100-ft. terrace.

The Swanscombe associated implements and flakes have been examined by the Abbé Breuil, who classes them as belonging to the St. Acheul 1 and 3 divisions of his nomenclature. The Swanscombe skull may therefore be referred to the St. Acheul 3 culture phase of Breuil.

The Swanscombe associated fauna is being examined separately by Mr. M. A. C. Hinton.

Mass Equivalent of the Energy in Radioactive Transformations

WITH a spark between a lead electrode and an electrode of palladium or one made of a platinum rhodium alloy, it was found that doubly-charged lead ions were formed, which in the mass-spectrograph gave close doublets with the singly-charged rhodium and palladium ions at 102, 103 and 104. The mass differences were $0{\cdot}0860 \pm 0{\cdot}003$ at 104 (Pd), and $0{\cdot}0861 \pm 0{\cdot}003$ at 103 (Rh). Although the packing fractions of palladium and rhodium have not been determined directly, they occupy a position on Dr. Aston's curve[1] where the divergence of the atomic mass from an even integer reaches its maximum value of approximately $0{\cdot}085 \pm 0{\cdot}005$. Assuming this value as applying to palladium and rhodium, we find a value for the atomic masses of the lead isotopes of $206{\cdot}00 \pm 0{\cdot}01$ and $208{\cdot}00 \pm 0{\cdot}01$.

It is of interest to deduce the atomic masses to be expected for the lead isotopes from the atomic masses of uranium (238·088) and thorium (232·070) given in a recent letter[1]. In the uranium series of radioactive transformations, eight α-rays and six β-rays are ejected with a total energy of 52 million electron-volts (43 in the α-rays, and 9 in the β-rays). In the thorium series, six α-rays, four β-rays and an energy of $43{\cdot}3 \times 10^6$ e.v. are emitted. The α-rays and total number of electrons lost by the radioactive elements are in the proper number to form neutral helium atoms[2] of a mass 4·0039. If we should neglect the mass equivalent of the energy, we would be led to expect mass values for the lead isotopes of $238{\cdot}088 - (8 \times 4{\cdot}0039) = 206{\cdot}057$ and $232{\cdot}070 - (6 \times 4{\cdot}0039) = 208{\cdot}047$. These are higher than the values deduced above by several times the possible experimental errors, and it is impossible to ascribe the discrepancy to uncertainty in the masses of palladium and rhodium, as it would be necessary to suppose that the masses of those elements diverge from integers by less than half the amount required by Dr. Aston's curve.

We have thus an example of the necessity of allowing for the mass equivalent of the energy emitted. As one million electron volts is closely equivalent to 0·001 mass units, the 52×10^6 e.v. and $43{\cdot}3 \times 10^6$ e.v. would reduce the expected mass of uranium lead to 206·005 and that of thorium lead to 208·004, which agree within the experimental error with the values deduced from the observations in the first paragraph. Unfortunately, the precision of the measurements is not yet sufficient to decide whether the maximum energy of the β-rays (9×10^6 e.v. and $6{\cdot}3 \times 10^6$ e.v.) or the mean energy must be considered, or even whether their energy has a definite mass equivalent.

Ranges of Particles Emitted in the Disintegration of Boron and Lithium by Slow Neutrons

I HAVE determined the ranges of particles emitted during disintegration of ^{10}B and ^{6}Li by slow neutrons, using a boron or lithium-coated ionization chamber connected with a Hoffmann electrometer. The ranges were deduced from the position of angles on the curves representing the ionization as a function of the pressure. The chamber filled with air was a brass cylinder of 8 cm. inner diameter and 10 cm. height. In the case of boron, pure finely powdered boron mixed with some water was distributed over the inner walls of the chamber; the density of the layer after evaporation of water was 2×10^{-3} gm./cm.^{2}. In the case of lithium, lithium hydroxide made insoluble by heating at a high temperature was spread over the surface in an analogous manner with the same density as before. About 10 millicuries of polonium mixed with beryllium were used as source of neutrons, and the chamber was surrounded with a large cylindrical block of paraffin wax for slowing down the neutrons.

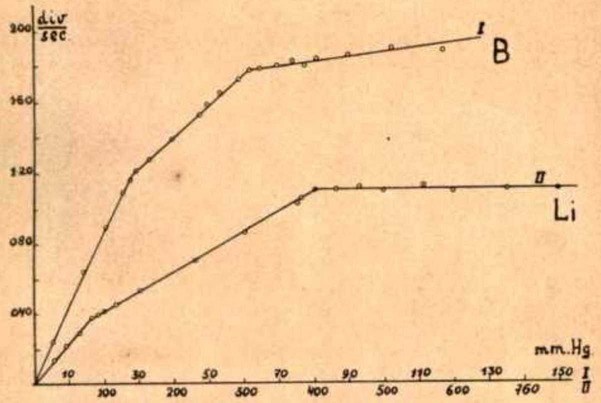

FIG. 1.

In order to evaluate the effect due to slow neutrons, measurements were made at each pressure (a) with neutrons filtered through a sheet of cadmium 0·5 mm. thick, (b) without cadmium. The difference $b - a$ is due to slow neutrons only.

These differences are plotted against the pressure of air on Fig. 1. The angles corresponding in the case of boron (Curve I) to α-particles and ^{7}Li nuclei, and in the case of lithium (Curve II) to α-particles and ^{3}H nuclei are well apparent. They occur respectively at the following pressures:

Disintegration of boron: α, 62 mm.; ^{7}Li, 27·6 mm.
Disintegration of lithium: α, 82 mm.; ^{3}H, 408 mm.

Owing to the shape of the chamber, the paths of particles *in vacuo* were of unequal length, and it was therefore necessary to define a 'mean effective length of path'. To do this, the apparatus was calibrated in the following way. To the boron powder a few drops of an extremely weak solution of polonium were added, and the substance spread over the walls in exactly the same manner and quantity as before. The ionization pressure curve gave 293 mm. for the position of the angle, which gives 10 cm. as the 'effective mean length of the path' of the particles. Using this value, I obtained the following values for the ranges:

Disintegration of boron: α, 8·18 mm.; ^{7}Li, 3·64 mm.
Disintegration of lithium: α, 10·8 mm.; ^{3}H, 53·6 mm.

The ranges for α-particles correspond to the energy $E_{a\mathrm{B}} = 1 \cdot 43 \times 10^6$ e.v. and $E_{a\mathrm{Li}} = 1 \cdot 93 \times 10^6$ e.v. respectively[1].

Owing to the conservation of quantity of movement, the total kinetic energy of the emitted particles is equal to $\frac{m' + m_a}{m'} \times E_a$, E_a being the energy of the α-particles, m' the mass of the nucleus emitted simultaneously with the α-particles (namely, ^{7}Li in the case of boron and ^{3}H in the case of lithium). If the disintegration is not followed by any γ-ray emission, this kinetic energy represents the total energy, E_B and E_Li, released in the nuclear processes under examination. Assuming this to be true, I find $E_\mathrm{B} = \frac{11}{7} E_{a\mathrm{B}} = 2 \cdot 24 \times 10^6$ e.v., and $E_\mathrm{Li} = \frac{7}{3} E_{a\mathrm{Li}} = 4 \cdot 5 \times 10^6$ e.v.

Using the following atomic masses[2], $n = 1 \cdot 0091$, $^{3}\mathrm{H} = 3 \cdot 0171$, $^{4}\mathrm{He} = 4 \cdot 0039$, $^{6}\mathrm{Li} = 6 \cdot 0167$, $^{7}\mathrm{Li} = 7 \cdot 0180$, $^{10}\mathrm{B} = 10 \cdot 0161$, I find $E_\mathrm{B} = 0 \cdot 0033$ mass units, or $3 \cdot 07 \times 10^6$ e.v., and $E_\mathrm{Li} = 0 \cdot 0048$ mass units, or $4 \cdot 48 \times 10^6$ e.v. The agreement is excellent in the case of lithium, while in the case of boron the discrepancy is greater than could be attributed to errors in the determinations of ranges. If instead of the experimental velocity-range relation given by Blackett and Lees, we use the numbers calculated from the theories of Bethe and of Bloch[3], then the agreement is in both cases within probable experimental errors. It may also be noticed that Curve I for boron shows a slight increase even at pressures at which the ionization should be constant. This increase may correspond to an unknown mode of release of energy, perhaps related to the existence of γ-rays of boron, reported by Kikuchi, Aoki and Husimi[4].

The cross-section of the boron nucleus for capture of a slow neutron was found to be eight times greater than the cross-section of the lithium nucleus.

My thanks are due to Prof. L. Wertenstein for his interest in this work.

Kikuchi Lines from Etched Copper Crystal

IT is well known that a cross-grating pattern of spots is produced when a fast electron beam is incident, at a small angle, on the etched surface of a single crystal. Two explanations have been given of this phenomenon. Thomson[1] showed that the effect would arise if the electrons passed through small projections on the surface, while Germer[2] attributed it to distortion of the crystal lattice. When etched single crystals of zincblende and galena were studied by Tillman[3], he found Kikuchi lines to be present in addition to the cross-grating and, as has been pointed out previously[4], the presence and sharpness of Kikuchi lines may be taken as a criterion of the degree of perfection of the crystal lattice.

It has been found that an etched single crystal of copper gives Kikuchi lines along with a cross-grating of spots (Fig. 1). The crystal was cut from a freshly prepared single-crystal rod which had been carefully protected from any distortion. Subsequent specimens, cut from the same rod and etched in the same way, did not give Kikuchi lines, due to the inevitable slight bending of the rod during the first sawing operation. The Kikuchi lines observed were not so sharp as those from zincblende and galena but, nevertheless, they do not indicate a degree of distortion sufficient to allow the formation of a cross-grating pattern in the way suggested by Germer.

Chemistry of Growth Substance *B*

SOME years ago, we found[1] that a growth substance acting upon *Aspergillus niger* and other moulds was produced when sugars (both pentoses and hexoses) were heated in a solution which also contained some organic acids or salts of these acids. This growth substance only acts when small amounts of ten different metals are added[2]. Also the growth substance produced by moulds or the growth substance extracted from plants, urine, etc., needs these metals to be able to influence the growth of moulds. We called these metals 'co-growth substances'.

TABLE I.

Added per 50 c.c.	Dry weight in mgm.
1·0 mgm. pyruvic acid	219
0·3 mgm. glycolic acid	167
1·0 mgm. pyruvic acid + 0·3 mgm. glycolic acid	343
No addition	132

A continued investigation has shown that this growth substance is produced when sucrose is inverted by means of organic or inorganic acids. For example, a solution of 25 per cent sucrose may be inverted by hydrochloric acid at room temperature. If some of this sugar solution is added to a culture of *Aspergillus niger* after the hydrogen ion concentration has been adjusted, the growth of *Aspergillus* will increase very much. An attempt to purify the active substance is not yet finished; but it has been shown that glycolic acid and pyruvic acid act as growth substances upon *Aspergillus niger*. Glycolic acid or pyruvic acid alone have little or no effect on the growth; but when added together they have a considerable effect.

It is seen from Table 1 that the growth of *Aspergillus niger* is more than doubled by the addition of glycolic acid and pyruvic acid. Some other organic acids also seem to have some influence on the growth. Thus ascorbic acid has a rather large effect when added together with glycolic acid and pyruvic acid, but not alone. Glyoxylic acid seems to have a very strong growth-accelerating influence when added alone or together with the glycolic acid and the pyruvic acid (Table II).

TABLE II.

Added per 50 c.c.	Dry weight in mgm.
1·0 mgm. pyruvic acid + 0·3 mgm. glycolic acid	451
1·0 mgm. pyruvic acid + 0·3 mgm. glycolic acid + 10·0 mgm. glyoxylic acid	551
10·0 mgm. glyoxylic acid	503
No addition	252

The growth substances which act upon *Aspergillus niger* and other moulds are very resistant to oxidation. If a mixture of different plant growth substances is oxidized by means of potassium permanganate or hydrogen peroxide the growth substances which act upon yeast are destroyed, whereas the growth substances acting upon moulds are not destroyed. In this way the two groups of growth substances may be separated.

Relative Velocities of the Absorption of Different Sugars from the Intestine of Rat and Pigeon

THE different velocities, with which various simple sugars are absorbed from the intestine, are among the outstanding facts which demonstrate the active part played by the intestinal mucosa during absorption. Cori[1], for example, finds for the ratio of the absorption velocities of *d*-galactose, *d*-glucose, *d*-fructose, *d*-mannose, *l*-xylose and *l*-arabinose in the rat: 110 : 100 : 43 : 19 : 15 : 9; while Verzár's pupils Wilbrandt and Laszt[2] find 115 : 100 : 44 : 33 : 30 : 29; and McCance and Madders[3] for the ratio of the last two sugars 44 : 25. According to Verzár and his collaborators, the absorption of the hexoses is inhibited by monoiodoacetic acid in contrast with that of the pentoses *l*-xylose and *l*-arabinose, which should not be affected by it. This, combined with the fact that they found equal absorption velocities for these two sugars, leads them to conclude that the absorption process in the case of the pentoses is a simple diffusion from the gut to the blood.

Now, I have shown[4] that the absorption velocities of glucose, galactose and fructose are largely affected by the composition of the diet to which the rats are accustomed, at least when there is only a short fasting period before the beginning of the absorption experiment. There is a real adaptation of the absorption to the presence of these sugars in the diet: the absorption of glucose is increased by the presence of glucose, fructose or galactose in the diet, compared to a carbohydrate free diet; the absorption of fructose, however, is more specifically stimulated by fructose, the absorption of galactose by galactose in the diet.

From these data several further questions arise. First, has the sequence of absorption velocities, as cited above, a general meaning, or is it more or less a casual product of dietary conditions? Secondly, what are the relative velocities of xylose, and arabinose absorption, those of Verzár and his associates, or those of Cori and those of McCance and Madders? If the latter authors be right, is there really a contrast between the hexoses and xylose as regards monoiodoacetic acid intoxication? Does the ratio of the velocities hold only for the rat, or is it general? Lastly, if it is shown to hold for other animals, at what stage of evolution does it appear first?

I have been carrying out experiments on rats and pigeons which for five days had been on a diet consisting only of fat, casein and salts (no vitamins, as I feared to introduce carbohydrate with the yeast). The rats showed the following series of absorption velocities : *d*-galactose : *d*-glucose : *d*-fructose : *d*-mannose : *l*-xylose : *l*-arabinose = 108 : 100 : 42 : 15 : 13 : 2; the pigeons gave 115 : 100 : 55 : 33 : 33 : 16. Thus there is no essential difference between my results with the rat and Cori's, and also there is no fundamental difference between the rat and the pigeon. Thus the same relationship holds for two species belonging to different, though not quite remote, classes. The smaller differences may easily be explained by differences of technique.

The pigeon showed itself much more sensitive to monoiodoacetic acid than the rat. Doses which did not kill it in two hours did not affect glucose absorption. In the case of the rat, however, not only inhibition of glucose absorption was observed, but also of xylose absorption. I believe that it is quite possible that the inhibitory effect of monoiodoacetic acid is not a direct influence on the metabolism of the intestinal mucosa, as Prof. Verzár thinks, but is a consequence of its disturbing effect on the circulation system.

A full account of my experiments will be given in *Arch. néerl. Physiol.* Experiments with lower animals have been started.

Several Spontaneous Chromosome Aberrations in *Drosophila*

THE solution of the problem of the phylogeny of the *Drosophila* species requires, in addition to a comparison of the structure of the chromosome in the salivary gland nuclei of related species, also a study of the spontaneous chromosome aberrations. Dubinin, Sokolov, Tiniakov[1] have found a large number of highly concentrated inversions in autosomes in populations of *D. melanogaster* and *D. funebris* taken from different places, but they have found no inversions in the *X*-chromosome, nor no translocations and no deficiencies.

Mass cultures may be compared to a certain extent with populations distributed on a small area, especially when the hatched flies are transferred on to fresh food without being selected. During six months, I studied the salivary gland chromosomes of four *Drosophila* species (*hydei*, *repleta*, *sulcata* and *lugubrina*) taken from such mass cultures. I found six spontaneous aberrations, of which only three were inversions in the autosomes (one in *D. repleta* and two in autosome II of *D. sulcata*). The other three spontaneous aberrations were chromosome rearrangements which have not been discovered in Nature by Dubinin, Sokolov and Tiniakov, namely, a deficiency in an automosome of *D. lugubrina* and two inversions in the *X*-chromosome of *D. sulcata*.

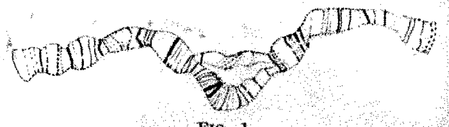

FIG. 1.

A heterozygous deficiency in one automosome limb of *D. lugubrina* (Fig. 1) was detected in about two-thirds of the number of larvæ in one culture; this heterozygous deficiency is retained in mass cultures throughout eight months.

The heterozygous inversions in the two limbs of the *X*-chromosome of *D. sulcata* (Fig. 2) belong, strictly speaking, to two different haploid chromosomes. They occurred independently of each other in two different mass cultures and were retained for several months.

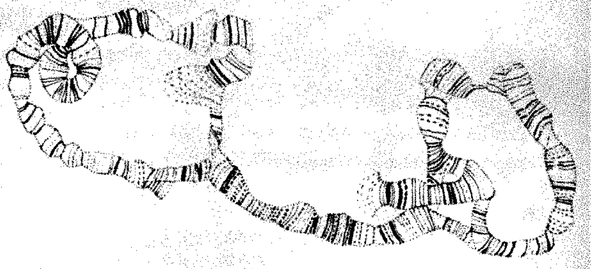

FIG. 2.

In these cultures the females heterozygous for inversions in the right or left limb of the *X*-chromosome were much more numerous than normal ones, and in addition to normal males there were males with an inversion in one of the limbs of the *X*-chromosome. Only owing to the viability of the males with an inversion in the *X*-chromosome could both inversions join in one individual in the case when a chance intermixture of flies from two different mass cultures occurs.

Of course, females with two inversions simultaneously may be only heterozygous. Females homozygous for inversions in one of the limbs are theoretically possible, but in fact they have not been detected either in mass nor in individual cultures. These females are apparently non-viable, this being proved by the numerical predominance of the males in individual cultures, where one of the inversions in the *X*-chromosome has been detected in the larvæ.

Two inversions in both limbs of the second autosome of *D. sulcata* belong to one chromosome because they are always detected simultaneously. No individuals, homozygous for these inversions, have been found. Chromosome II, heterozygous for both inversions, was found in one of the cultures where both inversions of the X-chromosome had been detected. Consequently, in this culture a small number of larvæ with a normal chromosome set and individuals with combinations varying between normal chromosomes and inversions both in the X-chromosome and autosome II were observed; which phenomena may also take place in populations in Nature.

The Teaching of Science in Schools

WITH much of what Mr. H. S. Shelton says on the subject of science teaching in schools, in his letter in NATURE of July 18, every teacher will agree. For example, closer association of prominent men of science with secondary education would be welcomed and would be most desirable. It is probable, too, that if another Committee were appointed, similar in constitution to that which sat in 1916–18 under the chairmanship of Sir J. J. Thomson, it would perform valuable service.

Unfortunately, however, Mr. Shelton includes in his letter a number of statements which may mislead those not closely in touch with what is happening. In the first place, it is inaccurate to say that the recent conference on general science represented a belated attempt to implement the (Thomson Committee) recommendation "That the science work . . . should include . . . some study of plant and animal life". The title given to the conference meant what it said and, as a matter of fact, far more schools include biology in their curriculum than Mr. Shelton probably recognizes. Before long, there will be few which do not.

Nor does the sub-committee appointed by the Science Masters' Association to consider the teaching of general science propose (as Mr. Shelton hints) to recommend a time-allowance of three hours per week. On the contrary, its members heartily endorse the original Thomson Committee recommendation that "the time given to science should be *not less* . . . than 6 periods". They would, indeed, prefer a more generous allowance than this.

Facts must, however, be faced: in many schools the recommendation has not been implemented. So that the report might prove useful to teachers in such schools, and so that it might not be merely an academic curiosity, the sub-committee has decided to work out two distinct syllabuses, of which the one to which Mr. Shelton refers is the less important.

When Mr. Shelton writes "If this proposal comes into being, we shall be back again in pre-scientific times", he seems to me guilty of pessimistic exaggeration. By "proposal", I suppose he means the publication of a syllabus, since no one proposes to recommend diminishing the time allowance given to science. It is very unlikely, after all, that the publication of a syllabus—explicitly stated as intended for schools giving a meagre time allowance to science—will encourage the more enlightened headmasters to curtail the time given to the subject in their own schools.

Lastly, I cannot subscribe to Mr. Shelton's statement that "The whole problem of the school time-table is now in hopeless confusion. No attempt is being made, for example, to correlate the mathematics and the science . . ." Confusion is, on the whole, less than it was and in many of the best schools a genuine attempt is being made to achieve some degree of correlation and to act on the recommendations of the various committees which have already considered the matter.

Dissociation Energy of Diatomic Sulphur, Selenium and Tellurium Vapours

ON the basis of the spectroscopic data of Naudé and Christy[1], Montgomery and Kassel[2] have recently calculated F^0 values for S_2 and the dissociation constant for the equilibrium $S_2 = 2S$. Their log K values are smaller by nearly 3 units than the experimental data of Nernst and v. Wartenberg[3] at 2290° and 2350° K. Although these latter values may be somewhat erroneous, it seems highly probable that they give the right order of magnitude. The necessary corrections to Montgomery and Kassel's calculations according to the data on vibrational and rotational levels[4] cannot explain this difference.

However, if we assume that the products of predissociation of S_2 at $4{\cdot}41 + 0{\cdot}02$ v.[5] (Montgomery and Kassel have used the value 4·45 v.) are $S(^3P) + S(^1D)$ instead of two normal ^3P atoms, we get $D_{S_2} = 3{\cdot}28$ v. and the dissociation constant falls within the limit of error of Nernst and v. Wartenberg's measurements.

The dissociation measurements of Nernst and v. Wartenberg allow also of the calculation of the dissociation energy of Se_2 and Te_2, although the necessary spectroscopic data are not yet sufficient for a high degree of accuracy. The accompanying table summarizes the thermochemical and spectroscopic values of the dissociation energies. In the case of sulphur, the normal state of the molecule is a $^3\Sigma$ state[4], whereas in the case of Se_2 and Te_2 it is not certain whether it is a $^3\Sigma$ or a $^1\Sigma$ state. In the table, the first value corresponds to the former, the second value to the latter case.

Dissociation energy in electron-volt

	from spectroscopic data	from equilibrium data at 2350° K.
S_2	4·41±0·02 or 3·28±0·02	3·2
Se_2	3·1±0·2[6]	2·7 or 3·1
Te_2	2·3±0·2[7]	2·0 or 2·4

With the value $D_{S_2} = 3{\cdot}28$ v., the equilibrium measurements for the three equilibria would be in good agreement; they would also be consistent with the spectroscopic data. If $D_{S_2} = 4{\cdot}41$ v. is correct, however, we would have to assume a very considerable error in Nernst and v. Wartenberg's measurements in the case of S_2, although the agreement is satisfactory for Se_2 and Te_2.

On the other hand, the value $D_{S_2} = 3{\cdot}28$ v. would mean that the dissociation products in the upper level of the main S_2-band system are not $^3P + {}^1D$ as in the analogous levels of O_2, Se_2 and Te_2, but probably $^3P + {}^1S$. Although there is spectroscopic evidence in favour of this solution[6], it is not quite satisfactory.

The two possibilities could be tested by measuring the energy of combustion of the SO molecule, which has been recently isolated by Schenk[8]. For this molecule as well as for S_2, two values are possible, $D_{SO} = 5{\cdot}05$ v. and $D_{SO} = 3{\cdot}92$ v., corresponding to the two possible interpretations of the predissociation at 5·05 v. A thermochemical cycle gives for the heat of combustion of SO, for the possible values of D_{S_2} and D_{SO}, the values 63, 77, 90 or 104 kcal., so that a measurement of that heat of combustion would give D_{SO} as well as D_{S_2}.

Note added in proof: In a recent paper[9], Olsson suggests the value 3·6 v. for D_{S_2} on the basis of his experiment on the induced predissociation. His interpretation of the process of induced predissociation is, however, not necessarily correct[6] and the value 3·6 v. does not agree with the attractive character of the S_2-level producing predissociation at 4·41 v.

Scattering of Light by Light

IN a recent paper[1] Euler and Kockel have calculated the effective cross-section for the scattering of light by light. The calculation was carried out for the case of small frequencies ($\hbar\omega << mc^2$), the frequencies being taken in a frame of reference, where the total momentum of the colliding quanta vanishes.

We have calculated the cross-section for the opposite case of large frequencies ($\hbar\omega >> mc^2$). For the integral cross-section we get an expression of the form:

$$\sigma = a\,\alpha^4\left(\frac{c}{\omega}\right)^2,$$

where $\alpha = \frac{e^2}{\hbar c}$ with a constant a, which is difficult to compute. According to Euler and Kockel, for small frequencies σ is proportional to ω^6. Consequently σ has a maximum value in a region $\hbar\omega \sim mc^2$.

It is also difficult to compute the dependence of the differential cross-section on the angle of scattering. We find that for the small angles the polarization of the light quanta is not altered. The differential cross-section for small angles is

$$d\sigma = 8\pi\,\alpha^4\left(\frac{c}{\omega}\right)^2 \log^4 \Theta\, d\theta,$$

Θ being the angle of scattering and $d\theta$ the solid angle. This formula is valid for small angles, but not essentially small compared with $mc^2/\hbar\omega$. In the latter case it is necessary to insert into the logarithm $mc^2/\hbar\omega$ in place of Θ.

The formula has a relative accurateness of $1/\log\Theta$. The cross-section increases with decreasing angles, but not very rapidly, and it is impossible to affirm that this region plays the main role in the integral cross-section.

The detailed calculations will appear elsewhere.

Mechanism of the Photo-Decomposition of Acetone

IN continuation of an investigation which has been reported elsewhere[1], an attempt was made to produce free methyl radicals by the photo-decomposition of acetone. According to Norrish, Crone and Saltmarsh[2], the radicals are produced by the following mechanism:

$$(CH_3)_2CO + h\nu \rightarrow 2CH_3 + CO$$

which is based on the latter authors' observation that at 60° the main products are equal volumes of carbon monoxide and ethane.

At room temperature, however, we were unable to obtain this equivalence, the volume of ethane being always 1·5 times that of the carbon monoxide. Furthermore, we were able to isolate diacetyl from the liquid products in considerable quantity, determine its boiling point and prepare several derivatives. Diacetyl has previously been detected in the products of photo-decomposition of aldehydes and ketones by Barak and Style[3].

Further experiments with filtered light of different intensities and with different concentrations of acetone suggest that the primary photo-chemical process is:

$$(CH_3)_2CO + h\nu \rightarrow CH_3 + CH_3CO.$$

However, when the photolysis is carried out at 60°, approximately equal amounts of carbon monoxide and ethane are formed together with some methane, the acetyl radical evidently being extremely short-lived at this temperature.

A detailed account of the experiments will be given in a forthcoming publication.

Proposed Suspension of Rules of Nomenclature in the Case of Bohadsch 1761

THE undersigned invites the attention of the zoological profession to the fact that application has been made to the International Commission on Nomenclature to suspend the Rules in Bohadsch 1761, "De Quibusdam Animalibus Marinis" and its translation 1776, on the ground that the application of the rules in these cases will produce greater confusion than uniformity.

Zoologists interested in this case, for or against suspension, are invited to present their views to the Commission.

Measurement of River Bores

WITH reference to the note in NATURE of April 25, p. 711, concerning the observations of the bore in the River Trent, may I direct attention to the observations made by the surveyors of Whangpoo Conservancy Board in February 1920 on the famous bore of the Ch'ien Tang River? Apart from general tide readings, special water-levels were observed every ten minutes during the day and every minute for one hour before and after the passing of the bore, at six stations covering a reach of 18½ miles, for two weeks. The maximum height of the vertical face of the bore was 4½ feet, the total rise in that tide being about 16 feet.

Representative figures, diagrams and photographs are given in the publication entitled "Report on the Hydrology of the Hangchow Bay and the Ch'ien Tang Estuary". This is now out of print, but a copy was deposited in the Science Library at South Kensington.

HERBERT CHATLEY.
(Engineer-in-Chief.)

Whangpoo Conservancy Board,
Shanghai.

The Beams Ultracentrifuge

AN ultracentrifuge designed by Beams has been in operation in this laboratory for the past year. From information published[1,2,3,4], we assumed the forces to be of the order of 5×10^5 times gravity when driven by air at about 80 lb. pressure. On subsequent measurement we find that the maximum force developed is 4×10^6 times gravity. This is obtained at a speed of 10,000 r.p.s., which is considerably in excess of that obtained by Beams[4] with a similar rotor under the same conditions.

The figures given in cytological papers from this Department therefore require correction.

A paper on the apparatus and methods of measurement is in course of preparation.

Points from Foregoing Letters

A DESCRIPTION of a new fossil human skull from the middle gravels of the Thames 100 ft. terrace at Swanscombe, Kent, is given by A. T. Marston. Its features are those of a specialized type less advanced than the well-known Piltdown skull. The author considers that the Piltdown skull must be assumed to come from a later geological horizon than the Swanscombe skull.

Values of 206·00 and 208·00 for the mass of lead isotopes are calculated by Prof. A. J. Dempster, by comparison with palladium and rhodium, by means of the mass spectrograph. This is in agreement with the atomic masses to be expected for lead isotopes derived from the radioactive transformation of uranium (238·088) and thorium (232·070), allowing for the loss of mass due to the emission of alpha-rays (helium) and beta-rays (electrons), and also for the mass equivalent of the energy of the emitted particles.

Graphs showing the ranges of particles emitted by boron and lithium (due to the capture of slow neutrons only) at different air pressures are submitted by J. Rotblat. Taking into account the most probable values of the masses of the particles involved in the transformation, the author finds in the case of lithium good agreement with the total energy calculated ($4 \cdot 5 \times 10^6$ e.v.). In the case of boron good agreement is obtained if the velocity-range calculated from the theories of Bethe and of Bloch is substituted for the experimental velocity-range relation given by Blackett and Lees. The boron curve indicates that there is an additional release of energy from boron, probably in the form of gamma-rays.

When a fast electron beam is diffracted by an etched surface of a single crystal of copper, Dr. W. Cochrane finds, in addition to the cross-grating pattern, also the 'Kikuchi' light and dark line pattern, which indicates a high degree of perfection in the crystal.

Data indicating the growth-promoting action of glycolic, pyruvic and glyoxylic acids upon the mould, *Aspergillus niger*, are given by N. Nielsen and V. Hartelius, in continuation of their investigation on the nature of the growth substance produced when cane sugar is inverted by means of acids.

Dr. H. G. K. Westenbrink shows that fundamentally the same ratio holds for the velocities of intestinal absorption of certain sugars (*d*-galactose, *d*-glucose, *d*-fructose, *d*-mannose, *l*-xylose and *l*-arabinose) with the rat and the pigeon. With both rat and pigeon there is a distinct difference between the velocities of absorption of *l*-xylose and *l*-arabinose.

Dr. S. L. Frolova describes and illustrates spontaneous aberrations of the chromosomes in mass cultures of several species of the fruit-fly, *Drosophila*. Of six changes observed, three were inversions in the autosomes of *Drosophila repleta* and *D. sulcata* and the other three consisted of a deficiency in an autosome of *D. lugubrina* and two inversions in the X-chromosome of *D. sulcata*.

A table summarizing the values of the dissociation energies of the sulphur, selenium and tellurium molecules, as deduced from both spectroscopic and thermochemical observations, is given by P. Goldfinger, W. Jeunehomme and B. Rosen. The authors state that a determination of the heat of combustion of the recently isolated sulphur monoxide would enable a choice to be made between the alternate values deduced from spectroscopic data.

A. Akhieser, L. Landau and I. Pomeranchook have calculated the cross-section for the scattering of light quanta by light quanta for the case of large frequencies.

Research Items

Early Man in New Mexico

In view of the discovery by Mr. E. B. Howard of stone artefacts attributed to Folsom man in association with the fossil remains of extinct mammals in what he termed "blow-outs" near Clovis, New Mexico, it is essential for chronological purposes that the geological character of these formations and the conditions in which the remains and artefacts were deposited should be clearly understood. This question was investigated by Messrs. Chester D. Stock and Frances D. Bode of the California Institute of Technology (*Proc. Acad. Nat. Sciences, Philadelphia*, **88**, 1936). The "basins"—a term preferable to either "blow-out" or "lake", which are misleading—are depressions, usually several hundred feet in diameter and two to ten feet in depth, in a long shallow trough, the Black Water Draw, from five to ten miles wide, which originates some thirty miles south-west of Clovis. The basins have been formed by wind-action, which has scoured the soil and underlying sediments of the centre, piling it up as sand dunes on the periphery, down to the Blue Sand (a blue-grey sandstone), which forms a smooth flat unbroken floor. As the Blue Sand is cut away—in the centre to a depth of four or five feet—flat benches with steep vertical banks develop. Residual areas capped by Blue Sand are left standing on the floor like islands. Erosion does not proceed beyond the Blue Sand. Probably the Blue Sand underlies the entire floor of Black Water Draw near Clovis. Masses of broken bones are found weathering out of the Blue Sand. These include bison, horse, elephant and camel. Flint chips are abundant on the floor of every basin, and several types of artefacts are associated with them. Artefacts of the Folsom or Yuma type occur only where the Blue Sand has been dissected. Convincing association with fossil mammal material was demonstrated in at least two basins, the Gravel Pit and Anderson Lake. Charcoal suggests a fire, but not necessarily of human origin, as it may be due to spontaneous combustion. The stratigraphic and physiographic relations of the Blue Sand to the present landscape suggest that it is possible to assign a very recent age to the deposit. It dates back to a pluvial period when the rainfall was greater than it is to-day; but this period does not necessarily fall into Pleistocene times.

Apparent Transformation of one Virus into Another

There are two inoculable tumour-diseases of rabbits, somewhat similar in appearance, and both caused by ultra-microscopic filterable viruses. One, rabbit myxoma, is malignant and always fatal; the other, rabbit fibroma, is never fatal and ultimately ends in recovery. A curious fact recently observed is that animals that have recovered from an attack of fibroma are unsusceptible to myxoma, and cannot be inoculated with it. According to Science Service, Dr. George Berry has reported at the meeting of the American Association for the Advancement of Science at Rochester, N.Y., that when active fibroma virus is mixed with myxoma virus killed by heating and the mixture injected into rabbits, the animals develop the deadly myxoma and die. That is to say, the benign fibroma virus by admixture with dead myxoma virus is apparently transformed into the myxoma virus. Controls with the dead myxoma virus alone had no effect. Further details respecting this important observation, which has been repeated many times, will be awaited with interest.

Microbiology of Australian Soils

The results of a study, at different ranges of temperature, of the rate of decomposition of organic matter in soil in relation to the numbers of micro-organisms present are detailed in a recent paper by Mr. H. L. Jensen (*Proc. Linn. Soc. N.S.W.*, **61**, 27–55; 1936). The decomposition rate was measured by the carbon dioxide production. In soils to which there had been no addition of organic matter, the carbon dioxide production was generally 100 per cent stronger at 28° than at 15° C., and some 50 per cent stronger at 37° C. than at 28° C. At each temperature, there was a significant correlation between daily yields of carbon dioxide and direct counts of bacteria. Growth of fungi was more extensive in sand soils than in loam soils, but no correlation was found between density of mycelium and yield of carbon dioxide. Decomposition of the soil's own 'humus' seems to be carried out almost entirely by bacteria, the accelerating influence of increasing temperature being due to stimulation of the metabolic activity of the bacteria. In soils to which various undecomposed plant materials (straw, hay, fungal mycelium) had been added, the rate of carbon dioxide production increased steeply with rise of temperature from 5° C. to 37° C. Significant correlations appeared between daily yields of carbon dioxide and densities of mycelium, and also between yields of carbon dioxide and direct counts of bacteria, but not between carbon dioxide yields and plant counts. The efficiency of the organisms decreased rapidly with advancing time. The fungi appeared to be important agents of decomposition during the earlier stages when the most intensive destruction of organic matter takes place. It is suggested that, especially at 28° C., their carbon dioxide production may considerably exceed that of the bacteria; with advancing degree of decomposition they cease to be of importance. The decreasing rate of decomposition of added organic materials, together with the increasing accumulation of microbial substance, seems to offer an explanation for the increasing accumulation of 'humus' with decreasing soil temperature.

Californian Shrimps of Commerce

Mr. Hugh R. Israel's researches on the commercial shrimps of California are interesting and instructive ("A Contribution Towards the Life Histories of Two Californian Shrimps, *Crago franciscorum* (Stimpson) and *Crago nigricauda* (Stimpson)". Division of Fish and Game of California. Bureau of Commercial Fisheries. Fish Bull., No. 46, 1936). Both species move towards the ocean as the spawning season approaches, and the eggs hatch in water of high salinity, the young shrimps migrating farther inshore into less saline water, and as they grow larger gradually moving into deeper water. Both species breed at the end of their first year, and soon afterwards disappear from the commercial catch, the main breeding season being December–May or June for *Crago franciscorum* and April–September for *C. nigricauda*. A very large catch of *C. franciscorum* in 1932 was made after the breeding season had ended, and one of *C. nigricauda* corresponded exactly with the breeding season. It is suggested that as in May and June 1933 the expected increase of this species did not occur, the heavy inroads made during the spawning season of the year before may be responsible. Very little is known about the planktonic larval stages of their shrimps, although it is presumed that they are similar to those of *C. vulgaris*. The latter species, however, may breed close inshore, and it would be useful to make a careful survey of the larvæ of these two Californian shrimps. The post-larval stages are taken at a considerable distance from the ocean in the shallow water of tidal flats and shoals.

Cercospora Leaf-Spot of Tobacco

A DISEASE of tobacco caused by the fungus *Cercospora nicotianæ* has attained severe proportions in the tropical areas of Queensland, Australia, the Dutch East Indies, Rhodesia and Nyasaland. The organism may produce spots upon leaves of the host at any stage of growth, and if it occurs in epidemic form shortly before the harvest, it results in a very destructive 'barn spot' during the process of curing. Mr. A. V. Hill has made a thorough study of the disease (*Bull.* **98**, Coun. Sci. and Ind. Res., Australia, Melbourne, 1936), and shows that it can attack twelve species of *Nicotiana*, in addition to the thorn apple and *Nicandra physaloides*. The optimum temperature for growth of the fungus is 26° C., and outdoor temperatures of this order, combined with rainy periods, greatly aggravate the effects of the malady. Seed from infected capsules is capable of transmitting the disease to a subsequent crop grown from it, and the main control measure lies in the use of healthy seed. Many other aspects of the problem are discussed in the paper, which has also seven excellent plates illustrating symptoms and the causal organism.

The Angiospermic Carpel

DR. I. V. NEWMAN has published (*Proc. Linn. Soc. N.S.W.*, **61**, 56–88; 1936) details of his studies of the floral apex of *Acacia longifolia* and *A. suaveolens*, which have induced him to champion the old theory of the origin of the carpel, and to criticize theories advanced in recent years by a number of investigators. After discussion of the evidence he concludes that (i) the legume is a lateral structure, (ii) the legume is a single, folded structure, (iii) the legume is not a foliar structure; and considers that in the two species dealt with there is no reason for doubting that the legume is of foliar nature and that it is reasonable to interpret the flowers of these species as modified leafy shoots. The subject has recently been under notice in the columns of NATURE (**137**, Jan. 11; March 14, 1936).

Lunar Periodicity of Earthquakes

OF the three laws that Perrey stated as governing the lunar frequency of earthquakes, the third, according to which earthquakes are more frequent when the moon is near the meridian than when it is at a distance of 90° from it, has suffered most from recent criticism. Mr. M. W. Allen (*Bull. Amer. Seis. Soc.*, **26**, 147–157; 1936) urges, however, that this criticism depends on statistics obtained from large areas, and takes no account of the strike or hade of the faults concerned. He has, therefore, considered the earthquakes during about forty-five years that originated within five or ten miles from three great faults in California. The earthquakes were grouped in different intervals of time, and harmonic analysis was applied to the numbers of shocks within lunar hour angles of 30°. Mr. Allen shows that, for the second harmonic alone, that associated with the semi-diurnal lunar effect, does the epoch incline towards constancy. Moreover, the amplitudes of this harmonic are more prominent than the others, ranging about 0·25 and being in some intervals nearly four times as great as that required by Schuster's test. It is thus difficult to escape the conclusion that "the semidiurnal lunar tidal forces have in some manner acted to determine the moment of occurrence of a significant number of the shocks of the region of the San Jacinto, Agua Caliente, and Elsinore faults".

Cosmic Rays

THE July issue of the *Journal of the Franklin Institute* devotes 81 pages to the report of the work of the Bartol Research Foundation 1934–35, made to the members of the Institute by Dr. W. F. G. Swann, the director of the Foundation. Almost the whole of the work during that period has centred around cosmic rays which have been investigated at ground-level, and at various altitudes up to 4,300 metres in Peru, Panama, Mexico and at stations in the United States up to 45° N. latitude. The 45 figures given enable the general reader to follow with ease the descriptions of the apparatus used and the results obtained. So far as they relate to the variation of the radiation with the latitude of the place of observation and angular distance from the zenith of the point from which they emanate they confirm the results of other observers, and they supply new facts as to the efficiencies of radiations from different directions in producing the secondary effects known as cosmic ray bursts. Dr. Swann concludes that the primary cause of the rays as measured is in the main an electrically charged particle of which the energy and the energy of the radiation measured is absorbed more rapidly when it is small than when it is large by its passage through the atmosphere.

The Compton Effect

IN the June issue of the *Review of Scientific Instruments*, Prof. E. L. Hill, of the University of Minnesota, reviews the recent work on this effect, and shows that the simple quantum theory of it, hitherto thought adequate, requires revision. That theory gives when a photon impinges on an electron: (1) the angle of deviation of the photon and its change of frequency, (2) the angle of recoil of the electron and its recoil energy, (3) that the three momenta concerned are coplanar and that the angles of deviation and recoil are related in a certain way. While conclusions (1) and (2) have been verified experimentally, the recent work of Dr. R. S. Shankland in Prof. Compton's laboratory has cast doubts on the simultaneous production of a photon deviation and an electron recoil which (3) assumes, and a revision of our corpuscular theories of radiation will be necessary. Dirac (NATURE, **137**, 298; 1936) has expressed the opinion that most of the present quantum mechanics may be retained, but that the quantum theory of the electro-magnetic field will probably have to be sacrificed.

Flagella Movement

By A. G. Lowndes, Marlborough College

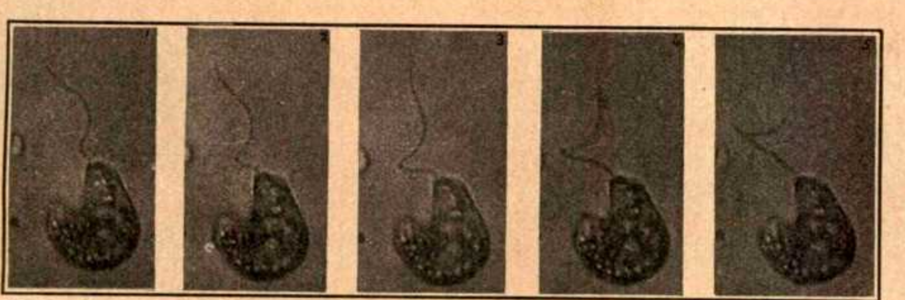

FIG. 1. *Peranema trichophorum.* Five consecutive exposures. Time of exposure, 1/8,000 sec. Interval, 1/30 sec. approx. The wave is clearly passing up the flagellum. The dark spot in the flagellum shows where a slight twisting occurs. This results in the extremity of the flagellum rotating. Measurement shows that the wave passes up the flagellum with an increase in velocity.

ALTHOUGH flagella movement or propulsion by means of a single flagellum is probably one of the first types of movement which came into existence, the fact remains that comparatively little is known for certainty about its actual mechanics. For example, it has always been a debatable point whether the flagellum is a passive unit mechanically operated by the cell, or an active structure developing partly or wholly its own energy. It is true that Gray[1] has given much evidence in favour of the latter view, but quantitative data are lacking. It has also been maintained in practically all standard text-books, that in all tractella or cases in which the flagellum is attached to the anterior end of the cell or organism, the waves of distortion pass from the tip of the flagellum to its base.

By the application of ultra-rapid cinema photomicrography[2] it has been possible to settle the one point and disprove the other. The flagellum is an active unit and generates its own mechanical energy. In the tractella of five species investigated, the waves of distortion start at the base of the flagellum and travel towards the tip.

Fig. 1 shows five consecutive exposures of the flagellum of *Peranema*, which is a very common monoflagellate with a so-called tractellum. The exact interval between the exposures is known, and so is the magnification. The distance from the base of the flagellum to the crest of the wave is easily measured, and on plotting this against the interval, it is established that the wave is passing along the flagellum with a definite increase in velocity.

Fig. 2 shows four consecutive exposures of the flagellum of the same species, but the flagellum is behaving rather differently. Both figures show, however, that a wave passes along the flagellum with an increase in velocity and also an increase in amplitude.

Reference to Fig. 1 also shows that as the wave of distortion passes along a flagellum, a certain amount of rotation of the distal end is caused, and if the energy output of such a flagellum is increased, the amplitude of the waves decreases while the frequency increases and thus a series of small waves is produced. This is illustrated to perfection in *Peranema*, in which the waves pass along the flagellum sufficiently rapidly to cause the tip to rotate rapidly while the proximal part appears to be rather stiffly extended.

The actual tip of the flagellum is bent round so that the impulses passing from base to tip actually produce a forward component, and it is only when the flagellum is extended in this manner that the organism swims forward with its maximum velocity (Fig. 3). The organism itself does not rotate as it progresses, nor does the base of the flagellum.

In *Euglena viridis* the waves of distortion pass along the flagellum as in *Peranema*, but the flagellum is bent right back from the actual base. The waves passing along the flagellum produce both a lateral and a forward component, thus causing the organism to rotate as it moves forward (Fig. 4). The net result is that, as the organism swims forward, its anterior end traverses a circular path at right angles to the long axis of the animal, while the whole of the animal rotates.

Now *Euglena* is highly metabolic, or in other words, it changes its shape rapidly. If the organism approaches or meets anything which normally would compel a reversal or change of direction, the organism immediately swells out at its posterior end and thus causes the anterior end to retract. This causes the flagellum to be swung forward, and the waves passing along it now constitute a powerful backward component, with the result that the organism either swings round with its hinder end acting as a pivot or it may actually swim backwards. When *Euglena* is swimming normally and is rotating, the flagellum appears first on one side and then on the other, and it is, of course, obscured in the intermediate positions.

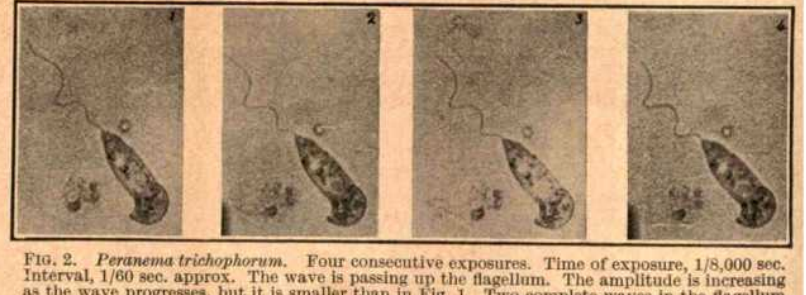

FIG. 2. *Peranema trichophorum.* Four consecutive exposures. Time of exposure, 1/8,000 sec. Interval, 1/60 sec. approx. The wave is passing up the flagellum. The amplitude is increasing as the wave progresses, but it is smaller than in Fig. 1. Two complete waves in the flagellum indicate an increase in frequency.

The rotation may be in a clockwise or anti-clockwise direction.

Altogether five species of monoflagellates have been investigated, and three of them filmed at considerable length. The action of the flagellum in all five species appears to be identical in outline, though quite different in detail.

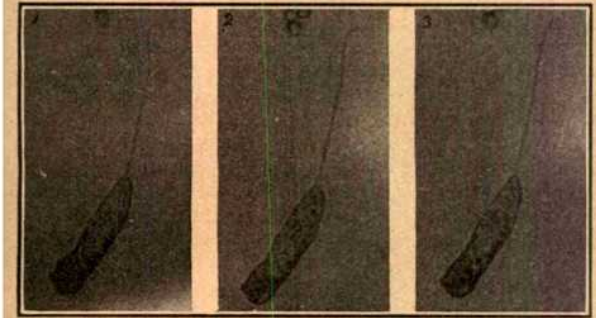

FIG. 3. *Peranema trichophorum*. Three consecutive exposures. Time of exposure, 1/8,000 sec. Interval, 1/30 sec. approx. The waves are confined to the tip of the flagellum. In this case, the organism is swimming forwards with its maximum speed. The extreme tip of the flagellum is not seen since it lies beyond the penetration of the objective.

To sum up: (1) The flagellum generates its own energy, at any rate in part, if not completely. (2) The waves of distortion pass from base to tip of the flagellum and not in the reverse direction. (3) The actual position taken up by the flagellum at any instant will determine whether these waves of distortion constitute a forward or backward component. (4) They may also cause the organism to rotate in a clockwise or anti-clockwise direction. (5) They constitute an important escape movement by causing the organism to reverse its direction rapidly without necessitating a reversal in either the direction of propagation of the waves themselves or the direction of rotation of the organism.

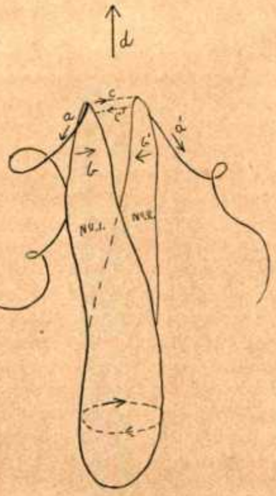

FIG. 4. Diagrammatic representation of *Euglena viridis*.

No. 1. A wave is passing along the flagellum in a direction *a*. This causes the organism to rotate in a clockwise direction *b*. It also causes lateral displacement of the front end of the animal *c*.

No. 2. The flagellum is now on the right of the organism. Either the same wave or another passes along the flagellum. Lateral displacement is in the direction *c'*. The organism is propelled in the direction *d*, and rotates in a clockwise direction. The anterior end moves in a circular path at right angles to the mean direction.

Specific Heats of Metals and Alloys at High Temperatures*

AFTER some ten years of experience in the investigation of various physical properties of metals at high temperatures, Prof. F. M. Jaeger and his collaborators at Groningen commenced, about fifteen years ago, the much more difficult investigation of the changes which the specific heats of metallic substances undergo at temperatures up to 1,600° C. At that time there were considerable differences in the data published by various experimenters regarding the specific heats of metals and their temperature coefficients at those high temperatures—differences which could not be accounted for entirely by variations in experimental technique, but which seemed to be due, in part at least, to unknown peculiarities of the metals themselves. As a result of the work of Prof. Jaeger, many of these discrepancies have been removed and much valuable information has been obtained concerning the nature of thermal and molecular transformations in the metallic state.

The direct specific heat measurements were carried out by means of a high-precision metal-block calorimeter in which temperature differences of a few millionths of 1° C. could be measured with certainty. The results obtained by the calorimetric technique were checked and confirmed by independent methods, for example, by measurements of the variation with temperature of the electrical resistance and of the thermo-electric behaviour of the metals. In studying the variation of any such property as a function of temperature, use was also made of two optically coupled galvanometers combined with a photographic recording device in order to obtain continuous curves, which immediately reveal any sudden discontinuity of the variable property at a particular temperature.

As regards the discrepancies in the results of previous workers, Prof. Jaeger's investigations show that these can be largely attributed to the measurements having been made with samples of metal which had undergone different preliminary thermal or mechanical treatment and which, therefore, were physically non-homogeneous due to the presence of inner stresses. Metals which have been suitably tempered by prolonged heating *in vacuo* at a constant high temperature as near to the melting point as possible, followed by slow cooling *in vacuo*, give values of the specific heat which, even at lower temperatures, are quite reproducible. This is especially striking in the case of silver, for which Prof. Jaeger has obtained a C_p-temperature curve which is concave to the temperature axis and not convex, as indicated by the best previously recorded data.

In many cases, the behaviour of metals at high temperatures is complicated by the occurrence of allotropy, and the calorimetric method is particularly suited to the detection of such changes. The transformation to a new allotropic form usually commences at a much lower temperature than the thermodynamically defined transition point, and in this 'transition interval' the specific heat of the metal increases very rapidly with the temperature, often reaching extremely high values.

---

* Substance of a lecture by Prof. F. M. Jaeger, University of Groningen, delivered at University College, London, on May 11.

In passing through the transition point, either by heating or by cooling, the allotropic changes are frequently accompanied by certain retardation phenomena. For example, beryllium, which has been given a preliminary heating at temperatures of 450° C. or more and is then allowed to cool from 400° C., gives off the same amount of heat, but over a longer period, than a sample of the metal which has not been heated above 400° C. The change in the internal state of the metal brought about by the preliminary heating may persist for several months, but there is a continuous return to the original state. Similar changes have been observed with rhodium, zirconium, chromium, titanium, and other metals, and the phenomenon appears to be a very general one. It is interesting to note that in the case of beryllium, the retardation of heat evolution completely disappears if the sample of metal is previously finely powdered.

Another factor of importance is the remarkable influence which may be exerted by almost imperceptible traces of gases—chiefly of oxygen, but occasionally also of nitrogen and of hydrogen—on the phase changes which occur in metals. In the α-titanium $\rightleftarrows\beta$-titanium transition, for example, there is at the transition temperature of 882° an additional hysteresis effect, which disappears with a sample of metal prepared *in vacuo*, but returns on the addition of traces of oxygen and nitrogen.

Prof. Jaeger's experimental study of the specific heats of metals at different temperatures has provided more accurate data which can be applied to testing the validity at high temperatures of two important theoretical deductions. According to the quantum-theoretical treatment by Einstein and by Debye of the variation of the specific heat of solid substances with temperature, the atomic heat at constant volume of solid mono-atomic elements should, even at the highest temperatures, never exceed a value of $3R=5\cdot955$ cal. The experimental results make it improbable, however, that any such upper limit exists, since this value is already exceeded in most cases at relatively low temperatures. The second application concerns the validity of the Neumann-Kopp law, which states that the molecular heat of a compound is an additive property of the atomic heats. Prof. Jaeger's measurements show that, in the case of alloys, the law is obeyed only when true solid solutions are formed between the component metals. With intermetallic compounds, the deviations from additivity, which are sometimes very considerable, may be either positive or negative, and in all cases rapidly increase with the temperature of observation.

O. J. WALKER.

Insect Pests of Crops in England*

THE Ministry of Agriculture and Fisheries' report for 1932–34 on insects affecting crops has been drawn up by Mr. J. C. F. Fryer, in collaboration with his colleagues at the Plant Pathological Laboratory, Harpenden. In dealing with advances in the application of insecticidal measures, the subject of pyrethrum is again considered in this report. Methods for the evaluation of the toxic principles of pyrethrum, elaborated by Dr. F. Tattersfield at the Rothamsted Station, have proved valuable, and it has been further shown that the incorporation of certain antioxidants greatly retards the deterioration of pyrethrum dust when exposed to the air. The plant has been shown to grow, and to yield satisfactorily, under English conditions; but the available methods of harvesting entail too heavy labour costs to warrant cultivation as a paying proposition. This aspect, therefore, remains in abeyance, at any rate for the time being, but in view of the valuable properties of pyrethrum, and the safety attending its application as a spray fluid, we may hope that cultural difficulties will eventually be overcome.

The hot-water treatment of daffodil bulbs as a measure against the Merodon fly and nematode pests is now an established procedure, and the same method has now become applicable in respect to the *Tarsonemus* mite of the strawberry. The treatment has been further developed with reference to strawberries, chrysanthemums and violets.

Among introduced pests, the Colorado potato beetle is of great importance: the recent eradication of a slight infestation in the Tilbury–Gravesend area is a matter for congratulation to all concerned. But for the prompt measures put in force by the Ministry, this insect might have gained a foothold, and led to a veritable campaign for its eradication. The extent of its adopted area in France, and its continued spread in that country, will serve as a justification for the close scrutiny that is being maintained at likely English ports of ingress.

Among other foreign pests that have found entry into Great Britain, reports on the eradication of the chrysanthemum midge and fluted scale are satisfactory, and measures to preclude the introduction of the apple maggot and cherry fruit fly have given the effective results anticipated. During the period under review, many indigenous crop pests are mentioned. There were no very outstanding attacks on cereals but with regard to potatoes, the *Heterodera* eelworm was a serious menace and appeared to be spreading. Larvæ of chafer beetles were specially in evidence as pests of grassland, while in connexion with sugar beet cultivation, the discovery of the *Heterodera* potato eelworm in that crop has complicated the situation. Proper rotation and clean cultivation may avert the severe losses which this creature has brought about on the continent of Europe. *Brassica* crops came in for heavy infestation by the aphis *Brevicoryne*, flea beetles and the cabbage white fly—dry weather conditions seemingly having favoured such attacks.

Fruit pests are always numerous: the apple sawfly attracted most attention, but the application of proper measures, when carefully timed, reduced the menace to manageable proportions. The deterioration of strawberries has greatly concerned growers, and the discovery that the disease known as 'yellow edge' is carried by a prevalent species of aphis has added to the importance of the latter as a pest. Among glass-house troubles, the record of damage to tomato seedlings by a species of the order Symphyla during the three successive years under review is of interest. Much damage has been claimed as being due to such creatures in America in recent years, but the status of this species as a pest is not as yet universally accepted.

The report concludes with a useful bibliography of publications bearing upon the subjects dealt with.

A. D. I.

The Marine Steam Boiler

In a recent note on "The Future of Steam Propulsion", reference was made to a paper on the relative merits of steam and oil engines for ships (NATURE, 137, 267; 1936). The subject is one of considerable importance at the present time, when a period of increased ship construction is imminent, and a new and different 'battle of the boilers' such as occurred at the time of the introduction of the water-tube boiler into H.M. Navy may be anticipated. Two papers dealing with the matter were read before the spring meeting of the Institution of Naval Architects in April last. In one of these, a "Review of the Present Position of Marine Steam Boilers", Eng.-Rear-Admiral W. M. Whayman dealt with large high-speed ocean-going mail steamers and passenger liners; he holds that these services constitute practically an exclusive field for steam machinery. Asserting that oil is, at present, the only suitable fuel for such installations, he points to the fact that, where speed and passenger comfort are the main consideration, oil-fired water-tube boilers have been adopted for ocean liners in all countries, and he gives details of the boiler equipment of many well-known ships. Whereas pressures on shore approach 1,500 lb. per sq. inch at 900° F. the tabulated figures show that 400–450 lb. per sq. in. and 650°–740° F. constitute the generally accepted limits for high-class sea installations at present. It is suggested that by reason of the more severe conditions of sea service, these pressures and temperatures may be expected to remain fairly steady. It should, however, be recognized that since these special sea conditions must always exist, marine practice, while necessarily following land practice at a safe distance, will steadily advance as quickly as new methods, machinery and means of operation have been proved to be sufficiently reliable for service at sea.

The water-tube boiler, by reason of the much smaller diameters used as compared with the Scotch type, has enabled pressures to be nearly doubled, and the present tendency towards the elimination of the drum makes possible further advances in working pressures. Towards this end also the use of higher tensile alloy steels, the adoption of welding processes, the provision of air heaters, and the introduction of forced circulation, of pure feed supply and of methods of treating the steam between the turbines either by re-heating or by extraction of moisture, indicate the lines on which improvements may be anticipated.

In "Naval Water-tube Boilers", Eng.-Capt. S. R. Dight gave particulars of tests and experiments which have been carried out at the Admiralty Fuel Experimental Station, Haslar, with the object of obtaining more intimate information regarding the internal working conditions, and so enabling further improvements in efficiency and reliability to be made. Circulation was tested by means of Pitot tubes, and marked variations were noted between differently placed tubes, with occasional reversals occurring in fire-row tubes when sudden changes took place in the feed supply.

A device described as a circulation augmenter was introduced to enable the feed supply to assist circulation, and proved advantageous. The overheating of fire-row tubes, the use of air pre-heaters and of automatic feed regulators were among the subjects of test, and the general conclusion was that increase of output for the same space and weight was possible. The application of forced circulation is stated to be under consideration.

Breeding of Arctic Marine Prosobranchs*

DR. GUNNAR THORSON accompanied the Danish Three-Year Expedition to East Greenland in 1931–34 under the leadership of Dr. Lange Koch, and made extensive and regular collections of plankton from the southern main station of Ella Island during the period from January until September 1932. Later, these samples were supplemented by others collected by a Greenlander, Benjamin Samuelsen; thus giving a whole annual cycle of East Greenland plankton. In none of these samples and in none previously examined from these regions were there any prosobranchiate gastropods. This remarkable fact was partially explained by the large number of different prosobranchiate egg capsules with big embryos in the bottom samples and dredged material.

In order to investigate further, Dr. Thorson continued the collecting of gastropod egg-masses in 1932 and during the cruise of the *Godthaab* in the summer of 1933, and in addition examined material from other expeditions. By carefully studying the species in their various habitats and their distribution, and by comparing the embryos with the adults a good knowledge of the prosobranchiate fauna was obtained, with their breeding, resulting in the discovery that not one species has a pelagic larva, but all pass directly into the free bottom stage after they have reached a considerable size in their capsules. Alone of the twenty-eight Greenland molluscs noted (in twenty of which the breeding is described for the first time) *Acmaea rubella* was found to be viviparous and hermaphrodite.

---

* "Studies of the Egg-Capsules and Development of Arctic Marine Prosobranchs" by Gunnar Thorson. Treaarsexpeditionen til Christian den X's Land 1931–1934 under Ledelse af Lange Koch. *Medd. om Grønland*, 100, No. 5 (1935).

The present paper deals with the egg capsules and enclosed embryos, their breeding seasons and habitats (very characteristic in most cases). The young in the capsules were identified by comparing the shell with the apex of the adult, which is very different from the rest of the shell and gives a perfectly good clue to the embryonic period. Whenever possible the size and shape of the capsules, description of embryos, duration of embryonic state and number of embryos in each capsule are given. In many cases, especially in the large species, there are nurse eggs. In *Siphocurtus* about eight hundred eggs are laid in each capsule, of which usually only two develop into shelled embryos which devour the others. It is found that the number of embryonic whorls in a species is not always constant, but depends upon the conditions of nourishment in the capsules, and the time of escape of the embryos depends on the amount of nourishment.

The fact that these arctic species have no pelagic larvæ is very important, especially when we compare closely related species from Britain and elsewhere, and find that many of these have distinct veliger larvæ which often stay in the plankton until several whorls are attained. With the larger forms such as *Buccinum* and *Neptunea*, the young emerge in the crawling stage in both Arctic and British waters, but the British turrids and the species of *Natica* and *Velutina* whose larvæ are known all have well-developed veligers which remain in the plankton for a considerable time.

The author does not in this paper make any suggestions as to the special conditions in these Arctic waters which apparently prevent any pelagic prosobranch larvæ from living. One anticipates with interest a discussion on these general problems.

Radio Research in Australia

IT is with considerable satisfaction that those responsible for the organization of radio research in Great Britain will note the continued activity of the Australian Radio Research Board as shown by the seventh Annual Report for the year ended June 30, 1935, recently issued by the Commonwealth Council for Scientific and Industrial Research[1]. Some of the papers published during the year under review have already been noticed (NATURE, 136, 650; 1935) and further papers have just been issued in Report No. 9.

Investigations connected with the fading of radio signals and the transmission of waves through the ionosphere have been continued with the aid of fresh modes of attack and advances in technique. A new method of carrying out frequency-change emissions for the recording of interference fringes at the receiving station has been developed, involving the production and separation of modulation sidebands at the transmitter. It is pointed out that one of the methods of controlling the wireless signal variations, commonly known as fading, is to emit signals simultaneously on a number of adjacent carrier frequencies; and some preliminary experiments have been carried out to ascertain the possibilities of this technique as applied to radiotelephony circuits. In the field of atmospherics, observations of direction, wave form and intensity are being continued as a long-term investigation. Most of the evidence supports the now generally accepted view that every atmospheric originates in a storm centre and probably in an actual lightning flash. From the study of intensities of atmospherics from lightning at known distances, it has been estimated that the equivalent power of a lightning flash is about 2 kw. for a receiver tuned to 1,000 kc./sec. and with a band-width of 20 kc./sec.; the total peak radiated power is probably of the order of 100,000 kw. The application of the knowledge obtained in this work to interference with broadcast reception, to meteorology and particularly in reference to aircraft navigation at night, receives continuous consideration in Australia.

The Annual Report acknowledges the co-operation which the Radio Research Board has received from such institutions as the Postmaster General's Department, the Universities of Melbourne and Sydney, the Department of Defence, and the Commonwealth Solar Observatory and Meteorological Bureau. The Board also welcomes the indication of the way its staff is regarded by industry, given by the fact that two of its members have recently resigned to take up industrial appointments.

The other publication recently issued, No. 9 in the series of Reports of the Australian Radio Research Board[2], contains seven papers. The first two papers deal with the study of the magneto-ionic theory of wave-propagation. A graphical method to facilitate this study, worked out by Prof. V. A. Bailey, has been applied by Dr. D. F. Martyn to the calculation of dispersion, absorption and polarisation curves for five typical wave-lengths between 100 m. and 20,000 m.

In the third paper, Mr. J. H. Piddington describes an investigation of the causes of frequency variation of a dynatron valve oscillator, and indicates the manner in which such variations may be reduced. Two of the papers by Dr. G. Builder deal with certain aspects of circuit technique as applied to radio reception, while a third describes a useful and robust thermionic voltmeter having four ranges between 0–5 and 0–500 volts. The last paper in the Report is by Mr. Piddington, and this describes the principles and design of a novel form of harmonic analyser which operates by suppressing the fundamental frequency and measuring the harmonics with a cathode ray tube outfit or a thermionic voltmeter.

Educational Topics and Events

BIRMINGHAM.—Mr. C. G. Parsons has been awarded a Walter Myers travelling studentship to be used in research in the United States on anæmia.

The following appointments have been announced: Dr. M. Stacey to be lecturer and Mr. F. Smith assistant lecturer in chemistry; Dr. A. Lamont to be assistant lecturer in geology; Mr. J. W. Drinkwater to be lecturer in mechanical engineering.

CAMBRIDGE.—Mr. A. L. Hodgkin, of Trinity College, has been elected to the Michael Foster studentship in physiology, which is offered annually for the encouragement of research. The value of the studentship is £105.

At King's College, O. L. Zangwill and J. W. S. Pringle have been elected to Martin Thackeray studentships.

LEEDS.—The Lord Mayor of Leeds has given a capital sum to provide an annual prize in clinical dental surgery, to be known as the Percy Leigh Prize.

The following appointments have recently been made: J. C. Gregory, to be honorary lecturer in the history of science; Dr. Frank C. Happold, at present lecturer in pathology and bacteriology, to be lecturer in biochemistry; H. R. Noltie, to be lecturer in physiology; W. Hobson, to be part-time lecturer in physiology and hygiene; G. D. A. MacDougall, to be assistant lecturer in economics.

WALES.—At the University Congregation held on July 22 at Bangor the honorary degree of D.Sc. was conferred on Prof. A. A. Read, emeritus professor of metallurgy in University College, Cardiff.

ADULT education in the United States has in the past been academic in scope and method, depending in the main for its inspiration and agencies on the universities through their 'university extension' departments. With the inauguration in a number of States of large-scale projects on the lines of the Des Moines "Public Affairs Forums", it has entered upon a new phase in which it finds inspiration and objectives that are frankly political. In his bulletin "Education for Democracy: Public Affairs Forums" (Superintendent of Documents, Washington, price 10 cents), the United States Commissioner of Education attempts a partial answer to the question "How can we make democracy work?" The success of American democracy depends very largely, he holds, upon how much understanding of our common problems can be diffused among the people, and he suggests that such understanding can be most rapidly and effectively promoted through the instrumentality of public forums to be established throughout the country and conducted on the lines of those which have been for the past four years in successful operation in Des Moines. In this city of 140,000 inhabitants some twenty-five 'small-neighbourhood' forums, five large-district forums and one city-wide forum were attended in 1934 by 70,000 adults. Distinctive features of the system are: it is administered as a fundamental part of the public school system under the control of the local education authority; the forum meetings are conducted by expert leaders; corresponding with the varying size and composition of the membership various techniques are used.

Science News a Century Ago

Suspended Animation

THE *Indian Journal of Medical and Physical Science* of August 1, 1836, gives the following account of a man who submitted to be buried alive for a month and was dug out alive at the end of that period: "He is a youngish man, about 30 years of age . . . he generally travels about the country, and allows himself to be buried for weeks or months by any person who will pay him handsomely for the same. The man is said by long practice to have acquired the art of holding his breath by shutting the mouth and stopping the interior opening of the nostrils with his tongue; he also abstains from solid food for some days previous to his internment, so that he may not be inconvenienced by the contents of his stomach, while put up in his narrow grave; and, moreover, he is sewn up in a bag of cloth, and the cell is lined with masonry, and floored with cloth so that the white ants and other insects may not easily be able to molest him. The place in which he was buried at Jaisulmer is a small building about 12 ft. by 6 ft., built of stone, and in the floor was a hole about 3 ft. long, 2½ ft. wide, and the same depth, in which he was placed in a sitting posture, sewed up in his shroud, with his feet turned inwards towards the stomach, and his hands also pointed inwards towards the chest. Two heavy slabs of stone, 5 or 6 ft. long, several in. thick and broad enough to cover the mouth of the grave, so that he could not escape, were then placed over him. The door of the house was also built up, and people placed outside that no trick might be played. At the expiration of a full month the walling up of the door was broken and the buried man dug out of his grave. . . . He was taken out in a perfectly senseless state, his eyes closed, his hands cramped and powerless, his stomach shrunk very much, and his teeth jammed so fast together that they were forced to open his mouth with an iron instrument to force a little water down his throat. He gradually recovered his senses and the use of his limbs".

Disease in Elm Trees

AT a meeting of the Entomological Society held on August 4, 1836, a letter was read from Mr. Spence giving an account of the destruction of elm trees in the promenades of Dunkirk, Boulogne and Calais, by *Scolytus destructor*. The decay of the trees had there, as in many other cases, been attributed to wind, soil and various other causes; but the writer was convinced it was owing to the one he had assigned, regarding which he had gained much information. Mr. Westwood added some observations on the extensive injury sustained by the elm trees in Kensington Gardens, London, the majority of those on the south side being dead. He considered that the Society, having accumulated a large mass of information on the subject, should hold an official communication with the commissioner of Woods and Forests for the purpose of suggesting some means by which the ravages might be restrained, as they had already extended to the trees in Lord Holland's park and along the Western Road past Hammersmith. Some attempts at remedying the evil had recently been made with the young elms, by plastering them over with cow dung, which was, however, quite ineffectual, as the beetles might be seen in thousands running over the covered surface. The neglect of the authorities was a matter of regret, as there could be no doubt that entomological science would cure the evil.

Giraffes at the Zoological Gardens, London

A correspondent writing to *The Times* said that the Zoological Society, "which is now extended to about 3000 members held their monthly meeting for the first time on Thursday last [Aug. 4, 1836] in the room which has been fitted up for that purpose, as also for the scientific meetings which are held every fortnight, at the new museum in Leicester-square, the collection of preserved specimens having been removed from Bruton-street". In the report of the council read at the meeting it was stated that M. Thibaut, who had secured the giraffes for the Society, had now left England. The total cost and expenses connected with the four giraffes had been about £2,340. A building for their accommodation would be ready by October, and it was proposed to heat this by air which had passed through pipes surrounded by hot water, a plan suggested by Mr. Sylvester.

Terrestrial Magnetism in Chile

In its columns of Miscellanea, the *Athenæum* of August 6, 1836, said: "M. Gay, residing in Chile, has communicated to the French Academy of Sciences that at the time of the great earthquake in that country in February 1835, he observed great variations in the diurnal movements of the needle; but in the lesser shocks the variations were feeble. His observations amount to more than two thousand, all of which have proved to him, that magnetic phenomena are much more complete in that part of the world than in Europe; for instead of two daily movements he obtained three: one in the morning in the East, another in the middle of the day in the West, and a third in the evening to the East again. This triple movement he considers as permanent, and suggests the great chain of the Cordilleras as one of the influential causes."

Education of French Pharmacists

In the *Records of General Science* of August 1836 is a note on the French School of Pharmacy. The object of this School, it said, is to teach all the sciences connected with pharmacy, and to receive such apothecaries as in four trials prove they possess the requisite knowledge for exercising this profession. Every candidate must produce certificates of his having studied for eight years—of his having attained his twenty-fifth year, and must place in the hands of the treasurer the sum of 1,300 francs. The School consists of a director, a joint-director, ten professors, of which four are joint-professors, and a treasurer. The necessary examinations are two upon theory, one of which is upon the principles of the art, the other upon the botany and natural history of simple drugs, and a third and fourth on the practice of the art which last for four days and consist of at least ten chemical or pharmaceutical operations, which the candidate must perform himself, describing the process, materials and results. The existence of this establishment thus enables every apothecary in France to be a chemist; while in England, whoever heard of an apothecary being a chemist or of doing anything for the improvement of pharmacy?

Societies and Academies

Paris

Academy of Sciences, June 22 (*C.R.*, 202, 2021–2108).

Ernest Esclangon: Observations of the eclipse of the sun of June 19, 1936. Observations of Nova Cephei and Peltier's comet. The partial eclipse in France was observed under excellent conditions at Paris, Meudon, Besançon and Bourges.

Vito Volterra: The canonical equations of biological fluctuations.

W. Doeblin and Paul Lévy: The sums of contingent independent variables with lower restricted dispersions.

B. Hostinsky: Movements depending on chance.

Octav Onicescu and G. Mihoc: Statistical chains.

Charles Ehresmann: The notion of complete space in differential geometry.

David Wolkowitsch: A family of surfaces of the fourth order.

Victor Lalan: Two groups of transformations defined by geodesy.

Armand Rauch: Integral algebroids.

Henri Poncin: The search for the conditions of stability of a limiting surface of cavitation.

Léopold Escande and Georges Sabathe: Experiments on the piers of bridges or of mobile dams with aerodynamic profile.

Charles Bertaud: The star stream of Scorpio-Centaurus.

Roger Mérigoux: The movement of contaminated liquid surfaces.

Pierre Jolivet: A cause of the small power of electrostatic machines and a means of remedying this. The yield is increased by enclosing the electrostatic machine in a vessel containing air under pressure.

Alexandre Marcel Monnier and Joseph Bazin: A continuous voltage amplifier.

Pierre Girard and Paul Abadie: Molecular interactions and chemical affinity.

Ladislas Goldstein: Collisions of the second kind and electronic affinity.

Robert Forrer: Electrons, carriers in supraconduction.

Léon Capdecomme: The substitution of surfaces in comparisons of reflective powers by means of the microscope. Discussions of the magnitude of the errors and precautions to be taken for reducing them.

Lewi Herman and Mme. Renée Herman-Montagne: The absorption coefficients of the bands 4774, 5770 and 6290 A. of oxygen. As found by Janssen, the absorption varies proportionally to the square of the pressure. A table is given for calculating the optical densities of atmospheric oxygen for different zenithal distances, neglecting the influence of temperature.

Maurice Roulleau: The spectral transmission of developed photographic emulsions.

Mlle. Yvette Cauchois: Observation and measurement of the $L\alpha$ satellites for the elements 72, 73, 75, 83, 90 and 92. The presence of satellites has been definitely proved and this suggests the necessity of modifying or completing certain recent theoretical conceptions.

Aurelio Marques da Silva: The materialization of the energy of the β-rays of radium C.

Albert Portevin and Paul Bastien: The mechanical study of the malleability of various types of light and ultra-light alloys. A study of the best conditions for hot working of aluminium and its alloys with copper and magnesium.

Ernest Toporescu: The transformation of urea into ammonium carbonate. Some ammonia is produced by dialysing a solution of urea containing sodium chloride.

René Paris and P. Mondain Monval: The crystallization of zinc borate. A contribution to the study of the conditions of the devitrification of glass.

Mlle. Suzanne Veil: The Liesegang periodicity and the concentration of the reagent drop.

Raymond Zouckermann and René Freymann: The high-frequency absorption of various alcohols. For a given wave-length, going up a homologous series, the conductivity rapidly increases, tending to become constant starting with the term C_5. This fact does not follow from Debye's theory, nor from the experiments of Malsch.

Guy Gire and Fernand Rivenq: The hydrolysis of solutions of pentavalent vanadium.

Etienne Canals, Max Mousseron, Louis Souche and Pierre Peyrot: The Raman spectra of some substituted epoxycyclohexanes.

André Dupire: Contribution to the study of the borates of the polyalcohols. Pure boric esters can be obtained by azeotropic distillation with toluene.

Marcel Patry: Esters of polymetatelluric acid.

Pierre Legoux: The relations between the granitogneiss and the schists and quartzites in western Africa.

Marcel Gautier: The tectonic of the Nemours region.

Marcel Mascré: The action of acrolein on the structure of the plant cell.

Robert Quetel: The variations in the proportion of nitrogen in the lily-of-the-valley during forcing.

Emile Miège: Experimental cultures of the potato in Morocco in 1935 in the mountains and on the plain. Whatever the origin and mode of preservation of the tubers sown, the yields are always greater in the mountains.

Roger Heim: The relationship between *Lactarius* and certain Gasteromycetes.

Pierre Drach: The cycle traversed between two moults and the principal stages in *Cancer pagurus*.

Gabriel Guignon: The study of the blood circulation of the wings in Coleoptera and Orthoptera by means of nicotine.

Raoul Michel May and Mlle. Alice Frank: The replacement of an anterior foot by a grafted bulb, in the embryo of *Discoglossus*, and its relations with the law of bilateral symmetry of the neurones.

Amsterdam

Royal Academy (*Proc.*, 39, No. 5, 1936).

L. S. Ornstein, C. Janssen, D. T. J. ter Horst, C. Krijgsman and G. H. Frederik: Investigation of transformer oil. Physical studies of ageing.

W. H. Keesom and P. H. van Laer: Measurements of the latent heat of tin in passing from the supraconductive to the non-supraconductive state.

W. H. Keesom and A. Bijl: Comparison of platinum resistance thermometers with the helium thermometer from −190° C. to −258° C.

R. Weitzenböck: The theory of semi-invariants.

J. G. van der Corput: (1) Distribution functions (8). (2) On some Vinogradoff methods (3).

E. Cohen and A. K. W. A. van Lieshout: An electrical pressure dilatometer. Apparatus for the study of polymorphic transformations at pressures up to 200 atm.

A. H. Blaauw, Ida Luyten and Annie M. Hartsema: Accelerated flowering of Dutch irises (1).

J. J. van Laar: Variation of some thermal and calorimetric quantities along the two melting curves of helium.

A. G. Boer, E. H. Reerink, A. van Wijk and J. van Niekerk: A naturally occurring chicken provitamin D. The isolation and chemical nature of a provitamin D from cholesterol.

K. Mahler: An analogue to a theorem of Schneider.

H. Freudenthal: Partially ordered moduli.

J. Beintema: Crystal structure of barium antimonate. X-ray and crystallographic examination of $Ba\{Sb(OH)_6\}_2.2H_2O$.

D. Tappenbeck: Tertiary Foraminiferan rocks of Sipoera (Mentawei Islands).

W. van Tongeren: Mineralogical and chemical composition of the syenite-granite from Boekit Batoe near Palembang, Sumatra, Dutch East Indies.

H. A. Barker: Fermentation of some dibasic C_4 acids by *Aerobacter aerogenes*. The process involves an initial oxidation-reduction between two molecules of the substrate and a subsequent decomposition of the oxidized molecule.

B. van der Eyken: Dentition and teeth development in the irisforelle (*Salmo irideus*) (5). Palate and pharynx.

D. Wiersma: Imagination and attention during childhood.

A. Geesink, H. de Jong and F. J. Nieuwenhuyzen: Experimental catatonia produced by auto-intoxication. (2) Experimental catatonia after ligation of the arteria hepatica propria.

H. A. Meyling: The glomus caroticum and the sinus caroticus of the horse.

Cape Town

Royal Society, May 20.

Mrs. M. R. Levyns: Notes on the genus *Stoebe*. *Stoebe* falls into two well-marked sections based on distinct types of floral structure. One type is widespread in Africa and extends to Madagascar and Reunion. Distribution of species of this type is predominantly discontinuous. The other type (comprising most of the species) is almost confined to the south-west Cape and the species have, with few exceptions, a restricted and continuous distributional range. The distribution supports the view that the south-western flora at one time occupied a much larger area than it does to-day.

J. L. B. Smith: Fishes new to South Africa.

Vienna

Academy of Sciences, May 7.

Leopold Schmid, Siegmund Margulies and Sidonie Lenzer: Chemical investigation of amber.

Leopold Schmid and Hugo Körperth: (1) The colouring matter of the poppy (*Papaver rhoeas*, L.). (2) Examination of extracts of petals. The chemical nature of the colouring matter of ten flowers is given.

Georg Koller and Hermann Hamburg : Rhodocladonic acid.

Philipp Gross and Hans Suess : Thermal decomposition of dioxane.

H. Dostal and R. Raff : The mechanism of thermal polycondensation reactions.

B. Ormont and B. A. Petrow : Thermal decomposition of simple and complex cyanides with formation of alkali metals, with special reference to potassium.

W. J. Müller, H. Freissler and E. Plettinger : Anodic behaviour of gold-copper alloys in 5*N* hydrochloric acid and *N* sulphuric acid. The relative quantities of gold and copper dissolved out of alloys of various compositions are measured when these are made the anode in acid solutions.

W. J. Müller and E. Low : (1) The influence of the purity of aluminium upon corrosion in hydrochloric acid of varying concentration. (2) Theory of corrosion phenomena. Part 4. Application of the theory of local elements to the problem of corrosion.

Alfred Lichtenfeld and Karl Schwarz : The theory of Kikuchi lines studied by means of models. Light is transmitted through a 3-dimensional grating having a spacing of about 1000 λ and bright lines are formed on a screen behind the grating.

F. Seidl : (1) Electrical conductivity of solidified melts of Rochelle salt. Conduction in Rochelle salt is found to be ionic in nature. (2) Electrical behaviour of single crystals of Rochelle salt crystallized from saturated solutions in an electric field.

Herbert Haberlandt : Radioactive haloes in fluorite from Striegau.

Max Toperczer : Contribution of the data of the magnetic survey of Austria in 1930.0 to the study of the earth's magnetic field. (2) Improvement of some values of the vertical intensity.

Wilhelm Schmidt : Vertical motion in clouds studied by cinematograph pictures. Vertical motion of any part of a cloud is detected by placing two successive photographs of the cloud in a stereocomparator.

Norbert Lichtenecker : Glacier research in the Sonnblick in 1930–34.

F. Steinhauser : Probability of precipitation in the eastern Alps.

H. Tollner : Glacier winds on the Pasterze glacier.

Erhard Braumuller : The north boundary of the Tauern between the Fusch and Rauris valleys.

Siegmund Prey : The possibility of the emergence of the Dent Blanche nappe in the Sonnblick.

Gabriele Rogenhofer : Action of growth-promoting substances on bark formation in woody shoots.

Helmuth Zapfe : The possibility of aragonite surviving the fossilization process investigated by means of the Feigl-Leitmeier reagent.

Emil Abel and A. Bildermann : Kinetics of the oxidation of formic acid by iodic acid.

Walter Kosmath, Volkmar Hartmair and Otto Gerke : Contribution of plant physiology towards the assessment of the biological or balneological importance of the radioactivity of the treatment at Bad-Gastein.

May 14.

Franz Rinagl : The importance of the upper elastic limit. By making use of the bending of bars of various cross-sections, trustworthy values of the upper elastic limit are obtainable.

Purposes of University Education

IN the plea for devising an education which would secure for us representatives capable of co-operating intelligently with technical experts in constructive social enterprise and would also teach us how to choose them, which formed one theme of his Conway Memorial Lecture (see NATURE of July 25, p. 139), Prof. L. Hogben uttered a warning against the teaching of science for vocational purposes which deserves close attention. He raises essentially the same question regarding all education that was raised of university education by the recent report of the University Grants Committee (see NATURE of June 27, p. 1057), and the wider question should in fact be faced before we really formulate our answer to the question, what is the purpose of university education.

The valuable study of education for citizenship in secondary schools, issued early this year under the auspices of the Association for Education in Citizenship (London: Oxford University Press. 5*s*. to non-members; 3*s*. 6*d*. to members), directed attention to the inadequacy of indirect education for citizenship to-day. Experience has shown that a man with a good general education based on languages or science may be an excellent father, an excellent business or professional man and at the same time a bad citizen. The political world has become so complex and difficult that it is essential to train men just as consciously and deliberately for their duties as citizens as for their vocation or profession.

The monograph to which we have just referred proceeds to discuss how the direct teaching of citizenship may be achieved, particularly by linking it to the subjects at present taught in secondary schools. Prof. Doris L. Mackinnon, for example, suggests that it is a prime duty of the teacher of science to let the pupil understand from the beginning what are the responsibilities in common life which the scientific discipline lays on all those who have once submitted to it. Moreover, the suggestions in regard to the teaching of clear and of accurate thinking made by Prof. G. C. Field and Dr. R. H. Thouless are scarcely needed more in any section of the community than in regard to the training of the scientific worker.

The present unsatisfactory position arises in fact from the growing tendency towards vocational education, and perhaps more particularly the teaching of science for vocational purposes. Already this has invaded the public and other secondary schools and spread far beyond the universities and technical colleges. In a highly organized society political administration must be the vocation of certain people. It is also true that intelligent citizenship is no longer possible without some understanding of the place of science in the everyday life of the whole nation; and the teaching of science needs to be adapted to such requirements rather than to those of assisting the few to gain a livelihood in a particular way.

If, therefore, we could re-orientate the teaching of science in both post-primary and secondary schools so that it would be taught as part of the equipment of everyone for living in a scientific age, and not as the first stage in preparation for a career in science, we should have taken one step to facilitate co-operation between the technical expert and the political administrator. If, further, by means of training for citizenship on the lines advocated by the Association for Education in Citizenship, we could ensure that those entering a university had received at any rate some equipment in this respect before embarking on their specialized studies, we should be in a much sounder position to discuss the question of the quality and quantity of university education.

As the report of the University Grants Committee points out, the engineer, chemist, medical man or schoolmaster trained at a university is rightly expected to have received a sound technical training in the particular calling or subject he has studied. Whether he has also received that stimulation and enrichment of the whole mind which enable him to lead a fuller and more interesting human life, and to play more adequately his part as member or leader of the community, must depend at least partly on the way in which he has been prepared for the training he receives at the university.

If the tendency to specialize at a too early age, and particularly in the later years of school life, has had insidious consequences and needs to be resisted strenuously, at least it should teach us that there can be no hard and fast separation between secondary education and university education. One must be planned in relation to the other, and we cannot throw on the university stage the whole responsibility of training a man not only as a skilled worker but also as a member of society and a human being.

The special responsibilities of the universities in this field must of course be recognized. Industrial and commercial appointments are being thrown open to university graduates over an increasingly wide field. The growing extent to which leadership in commerce and industry, like that in national and local administration, is passing under the influence of professional men, means that the great majority of those who become leaders in the national life will continue to be drawn from those who have received a university training. No university can fail to recognize the opportunities of service in ensuring conditions of training which enable its students to go into the world with minds richly informed, unsleeping in the exercise of a critical intelligence and imaginatively alive to the human issues underlying the decisions they may be called upon to take.

The importance of giving due attention to these fundamental issues at the present time can scarcely be over-emphasized. Mechanization of thought is a peril in Great Britain as in other countries, and the suppression in the universities of several European and other countries of all independent thought and critical discussion of the principles of government, or of the meaning of life, throws a special responsibility upon British universities if the Greek tradition of candid and intrepid thinking about the fundamental issues of life is to be preserved for mankind.

Training for citizenship is a part of this wider question of training for life, but the two can scarcely be separated in any discussion of education to-day. Both the school and the university, each within its own limits, must endeavour to give its students a training for life, and this is even more important than training for a particular vocation or career. It is at last becoming more widely recognized that it is scarcely possible for a university to equip its students with the technical knowledge which might be expected to be of immediate use to them in any branch of industry they may enter on leaving the university. The detail of technical work can in fact be mastered only by practical experience after the student has left the university. The function of the universities in training scientific workers and technical men for industry is rather to give them such a knowledge of the principles of science and technology that they are able to bring trained minds to bear upon the understanding of practical problems which they encounter in their industrial or professional life.

The stimulation of thought, the widening of its horizons, the development of the faculty of judgment, and the evoking in its students of the energy of the soul in which Aristotle found the essence of true well-being, are the essential contributions to education which characterize the university rather than the schools. The dissatisfaction with many graduates of universities to-day is largely due to the fact that their primarily specialized training has robbed them of the essence of a university education and left them unequal to the demands which the major problems of life and industry make upon them when questions of value and judgment are involved. Moreover, specialization in itself is not so much criticized as premature specialization and the inadequate foundation upon which it is built, with the result that many of those completing long courses of study at a university in medicine or science, for example, are in danger of being uneducated persons.

Prof. Hogben showed convincingly in his lecture how ability to sort out the real issues, and to think clearly on the values as well as on the scientific and technical factors involved, are demanded to-day in our political leaders and in some degree in those who elect them. The professional aspects of after-life are to-day scarcely the major preoccupation of the universities, at least so far as they are not linked up with the wider question of training in thought which they give to their students and of the linking of thought to action.

It is no part of the duty of a university to inculcate any particular philosophy of life. Never, however, was it more important than it is to-day that it should stimulate and train its graduates to think strenuously about the great issues of right and wrong, of liberty and government on which for the individual and for the community a balanced judgment is essential to a rational life. Without overlooking the place of research in the functions of a university or the desirability of upholding the value of learning for the sake of learning, the linking of knowledge to action is of such supreme importance at the present time that even the research activity of the universities needs to be re-orientated so as to secure that the advance of knowledge proceeds on a more even front. Only when our research effort is directed in some relation to the fundamental needs of society can we hope to redress some of the evils which the rapid advance in the physical sciences as compared with the biological or social has brought in its train.

An undoubted consequence of the redistribution of our comparative research effort between the physical and the biological and social sciences in the way urged by Dr. Julian Huxley or Prof. W. McDougall, for example, would be not merely the fertilization of thought in the social sciences and the breakdown of barriers between them but also the stimulation of thought generally in these fields. As in the physical sciences, we might witness significant advances through the overlapping of traditional disciplines in several branches of knowledge.

Given this redirection of research effort and the stimulation of thought in social and biological problems, the training of men and women who will bring unprejudiced minds, critical powers and moral courage to bear upon the new and difficult problems which they must meet in this era of physical science should become much simpler. To some extent, the absorption of the graduate into industrial or other employment may become a simpler problem because he will be better fitted to take any place as an intelligent member of the community, though the warning of the University Grants Committee in regard to the limitation of the members of those entering a university needs to be kept in mind. Nor can we overlook the importance of that early training for citizenship which those entering a university should share with those whose school education finishes at the post-primary or secondary school education stage. There at least must be laid a foundation from which a university can fittingly start to impart, not a mere training for livelihood, but a training for life and for leadership, so that its graduates are distinguished by a sense of values, a wide vision and a capacity for the creative thought and judgment which require only the ripening of experience to enable them to bring a trained mind to bear on any of the problems with which they may afterwards be confronted in their professional, industrial or civic life.

Morphology of Muscles

The Cranial Muscles of Vertebrates
By Prof. F. H. Edgeworth. Pp. ix+493. (Cambridge: At the University Press, 1935.) £5 5*s.* 0*d.* net.

IN this large, copiously illustrated and splendidly produced volume, Prof. Edgeworth has brought together the knowledge which has been gained in the last hundred and fifty years of the comparative anatomy and embryology of the cranial muscles (and their motor nerves) in vertebrates The author is well equipped for this task. Though not a professional zoologist—he was for many years, until recently, professor of medicine in the University of Bristol—he has long been a worker on this subject "so far as medical practice and teaching permitted", and has become widely known from his many published observations which have added to our knowledge of the subject.

This memoir is a notable and important contribution to vertebrate morphology, and contains the most complete account which has been published of the homologies of the cranial muscles. Its scope may be indicated by mention of the principal subjects discussed in its chapters. They begin with a discussion of the embryonic head mesoderm and its segmentation, of the relation of the muscle plates of the head to the myotomes of the body, and of the number of the branchial segments. The author finds that in the cephalic mesoderm, premandibular, mandibular and hyoid segments are followed by a "branchial region" in which the number of segments varies in different phyla, and, as he has found, among the genera of any one phylum. He puts forward the view that this variability occurs not by the intercalation or dropping out of segments but by "the separation of the branchial region as a whole into a greater or a lesser number of segments than is usual in their respective phyla".

The chapters which follow show the extensive range of the author's observations on the development and anatomy of the cranial muscles in the vertebrates from the Dipnoi to mammals. The subjects dealt with include the external ocular muscles, the palato-quadrate bar in Ichthyopsida and Amphibia, the mandibular muscles and the palato-quadrate bar in Sauropsida, and the palato-quadrate and mandibular muscles in mammals.

Separate chapters deal with the hypobranchial skeleton and the hyoid muscles, the superficial facial and cervical muscles of mammals, and the branchial muscles. Considerable space is devoted to the description of the Cucullaris muscle, and the author presents a condensed but valuable account of this muscle throughout the vertebrates. The first stage in its phylogenetic history is represented in the Dipnoi, in which a muscle, the "constrictor branchialis V", extends back as a broad sheet, "whose ventral edge is attached to the pectoral girdle and coraco-branchialis V. Probably generally in Holocephali and Selachians it is developed from the dorsal ends of all five branchial muscle plates. These extend forwards and backwards and fuse together to form a longitudinal muscle, the anterior end of which becomes attached to the cranium and its posterior end to the shoulder girdle. It is innervated by a branch of the 'R. intestinalis X', the fibres of which can be traced from the caudal, exclusively motor, fibres of the vagus or vago-accessorius.

"A cucullaris is present in most of the Amphibia and in the Reptilia. In birds there is no cucullaris—its function is taken over by the cranio-cervicalis, which also extends from the head to the shoulder girdle, but is innervated by a different nerve, the N, hypoglosso-accessorius. In mammals a cucullaris is present, developed from the most caudal branchial plate, and extends back to the limb as a single band."

The number and complexity of the cranial muscles is illustrated by the fact that thirty-eight pages are required merely for a list of the synonyms used by different writers for individual muscles, a list which the author states is "far from complete". This section is notable, not only from the wide range of vertebrate forms, but also from the number of embryos at different stages of development which he has examined. Its value is enhanced by the number of illustrations given in corroboration of the facts stated in the text.

The author discusses at length some of the difficulties which arise in determining muscle homologies. The segment of origin of homologous muscles is in general constant from genus to genus and from phylum to phylum, but exceptions occur. Anatomists have long been accustomed to consider that the nerve supply to a muscle affords sound and reliable evidence of its homology, and this is generally the case, but again exceptions occur; the muscle plate of the mandibular segment is as a rule innervated by the fifth nerve, but in certain instances the seventh nerve may be the source of nerve supply, and this arises, according to the author, from the shortness of the first gill cleft.

The author has dealt more fully than is usual with the relation of nerve to muscle and not only with the peripheral pathway through which muscles are innervated, but also with the significance and the homologies of the groups of motor cells, spinal and medullary, from which the nerves are derived. Experimental evidence is made use of whenever possible to determine afferent from efferent fibres in different nerves, and a chapter is devoted to analysis of the groups of efferent cells in the "occipito-spinal motor cell column".

The aim of the author has been to ascertain what evidence the study of these muscles gives on the problem of the genetic relation of the vertebrate phyla "and so of the phylogenetic history of Man in the remote past". It may perhaps be doubted whether the material which he uses is capable of affording such information. The successive changes undergone by the developing embryo and its parts give only a general indication of phylogenetic history. The skeleton, the central nervous system and many of the viscera have been studied from this point of view, but have yielded no information of great significance on this problem. Where these systems have failed, it is scarcely to be expected that the study of muscles would be more fruitful, but the author's studies have led him to certain conclusions as to what were the characters of the ancestral forms from which the existing vertebrate phyla have originated, and these are given in detail in the final chapter.

No one who works, as the author has done, on broad problems of morphology can fail to have his interest excited in the significance of the whole embryological process and the variations in its details which occur in different forms. The author's attitude towards this problem is best expressed by some sentences which may be quoted :

> "The development of the cranial muscles gives much evidence of its purposeful character."
>
> "In some unknown way the growing organism appears to foresee future needs, and sets to work with such material as it has to develop the necessary structures along the lines followed by its ancestors".
>
> "Experimental embryology shows that the growing organism from the zygote upwards is a whole and not merely an aggregate of parts. Similarly, animals are psychological units, characterised by memory and purpose, by striving after ends in view. The variations in the development of homologous structures and in the structures by which the same functions are carried out show that this psychological factor is of great importance from the first."
>
> "This immaterial, non-spatial, teleological factor, the mind, can initiate and inhibit physico-chemical processes. Life, development of individual organisms and evolution are primarily due to this power."

In view of the size and form of this volume and the wealth of illustrations—there are 841 figures, clearly drawn and reproduced on special paper, pp. 301–493—the price cannot be considered unduly high, though it may restrict its circulation. It is indispensable to workers in vertebrate morphology, and the author deserves the highest commendation for the care, the skill and the wide range of his inquiries, and is to be congratulated on the completion of a work which is a credit to British zoology.

DAVID WATERSTON.

A Study of the Ephemeroptera

The Biology of Mayflies:

with a Systematic Account of North American Species. By Prof. James G. Needham, Dr. Jay R. Traver, Prof. Yin-Chi Hsu, assisted by Specialists in certain Subjects. Pp. xvi+759. (Ithaca, N.Y.: Comstock Publishing Co., Inc., 1935.) 7.50 dollars.

PROF. JAMES G. NEEDHAM, of Cornell University, the senior author of this book, has made a very valuable contribution to the knowledge of a little-known order, the Ephemeroptera. This biology has one outstanding feature of merit, it is original work. Prof. Needham has gathered around him a band of enthusiastic workers who have come forward and in their own words and under their own names, have told us of the results of their researches. Two of these workers appear with Prof. Needham as joint authors. The second author, Dr. J. R. Traver, has been responsible for nearly the whole of Part 2, the systematic description of the North American species, about five hundred pages, as well as a portion of Part I dealing with life-history and collecting. The third author, Prof. Yin-Chi Hsu, is responsible mainly for the chapters dealing with structure and anatomy. There are further chapters on anatomy under the pen of Dr. V. Knox.

This book is perhaps the most comprehensive that has ever been undertaken on the biology of the order. Pictet, in 1843, dealt with both anatomy and systematics in his "Histoire des Névroptères" ; Eaton's classic monograph on "Recent Ephemeridæ" was mainly systematic ; there have been sundry papers written by various authors since 1888, the date of Eaton's great work, scattered through entomological literature.

Prof. Needham's book will appeal, of course, mainly to the specialist, having regard to the fact that so large a proportion of its space is devoted to American systematic work ; but the biology proper, consisting as it does of no less than 236 pages, has an interest not only for entomological workers but is also of economic value to all who are concerned with the study of the food of fishes, in Great Britain, more particularly the trout.

Chapter i deals with the life and habits of the Ephemeroptera or, as they are perhaps unfortunately called in America, the mayflies. It is unfortunate because the title is misleading. Not only do these insects appear on the wing during every month of the year—at least they do so in Great Britain—but also the name mayfly in the fly-fisher's world is restricted in its application to species of *Ephemera*, and the fly-fisher's popular nomenclature may be traced back for nearly five hundred years.

While, generally speaking, the life of an ephemeropteron is not quite so ephemeral as the name would suggest, Prof. Needham tells us of a species, *Callibœtis fluctuans*, the entire life of which in the winged condition is restricted to some forty-eight hours, during which it emerges from the water, changes from the subimago to the imago stage, pairs, oviposits and finally dies. The mayfly proper, the British species, *Ephemera vulgata*, on the other hand, has been observed by the writer, at least two months after emergence, having been so long on the wing as to have darkened to nearly black.

America is a country of extremes, and this trite saying applies even to the Ephemeroptera, for we read here that instances have been recorded of these little insects swarming in such incredible numbers that camp fires have been extinguished beneath their corpses.

Several pages are devoted to the nymphal stages and then we come to Prof. Hsu's chapters on structure; not only are the external parts explained but the internal anatomy as well, with a final word which carries us through the insect's development moult by moult.

Dr. O. R. Smith contributes a chapter on the eggs and methods of oviposition. We learn that the females habitually fly against the breeze in order to maintain their position over a selected portion of the water: that some get rid of their eggs a few at a time, dipping over the surface; others drop them in a mass; and that others again crawl down under water and lay their eggs on stones and rocks.

Passing to Chapter xvi, we find some useful information on the economic value of the Ephemeroptera; then there is a chapter on collecting, preserving and rearing them in captivity, and finally we come to Part 2, which deals with systematics. It suffices to state with regard to this branch of the subject, that the known North American species number 507 grouped in 3 families, 17 subfamilies and 47 genera. Useful keys and tables are included, and the whole plan of this part has been extremely well constructed.

We have no hesitation in stating that this book is a very fine contribution indeed to entomological literature. MARTIN E. MOSELY.

Developments in Organic Chemistry

(1) Physical Aspects of Organic Chemistry
By Dr. W. A. Waters. Pp. xv+501. (London: George Routledge and Sons, Ltd., 1935.) 25*s*. net.

(2) The Chemistry of Natural Products related to Phenanthrene
By Prof. L. F. Fieser. Pp. xii+368. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1936.) 32*s*. 6*d*. net.

(3) Reactions of Organic Compounds
By Dr. W. J. Hickinbottom. Pp. x+449. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1936.) 16*s*. net.

(1) A TREATISE on the implications to organic chemistry of new conceptions of the atom is particularly valuable at this stage when the arbitrary ideas of the chemist have been largely justified. Electro- and co-valencies, and the semi-polar bond are now universally recognized, and the complex hypotheses of induced polarity and conjugation are receiving physical interpretation.

Just as the existence of polar and non-polar bonds has been admitted, it is now certain that both ionic and non-ionic reactions occur in organic chemistry. The latter resemble photochemical reactions, and include those like the pyrolysis of diazoamines, in which transient formation of free uncharged radicals must occur. Greater space is devoted to ionic reactions, which are induced by polar reagents, and generally involve carbonium anions and cations. Thus the properties of free radicals, which behave variously as non-polar radicals, or as cations, or as anions, receive an explanation. Molecular rearrangements result from the reconstruction of a carbonium cation, caused by an ionic reagent.

In dynamic isomerism, which involves an equilibrium between two forms, an ion wanders from one part of a molecule to another (prototropy or anionotropy) with consequent redistribution of valency bonds. The classical idea of tautomerism, that a single substance can react as if it had two structures, is revived in terms of wave-mechanical resonance, to which brief reference is made. The two structures differ only in electronic arrangement, neither representing the molecule, "but a hybrid intermediate between them, which cannot be represented by ordinary symbols, and has to some extent the properties of both" (Sidgwick). Conjugation and aromatic properties are discussed chiefly in terms of the theories of Ingold and Robinson, according to which an electromeric change may be induced in an aromatic derivative giving an activated molecule, the polarization of which determines further substitution.

The value of the book to students is enhanced by the use of the historical method of approach. In the more physical chapters, such as that on dipole moments, mathematical treatment is curtailed, but conclusions important to chemists are concisely stated.

(2) Structures containing polynuclear ring-systems based on the hydrogenated phenanthrene nucleus have been allotted to the morphine alkaloids, the sterols, sex-hormones and cardiac poisons. The dramatic manner of progress lends added interest to this monograph, which is a comprehensive interim report (the copious references include January 1936, and 70 per cent date from 1930) on a subject important alike to chemists and physiologists.

An account of the chemistry of phenanthrene itself is followed by a lucid treatment of the morphine alkaloids and resin acids, which deals with their genetic relationships, their phytosyntheses, and the problem of drug addiction. Throughout, relevant features of general or biological interest are described, so that the complex chemical side is put in its correct perspective. This is exemplified in the account of the cancer-producing hydrocarbons, which though not yet known as natural products are related to the latter, and generally contain a phenanthrene ring-system. That methylcholanthrene, the most powerful carcinogenic agent known, is a bile-acid degradation product has obvious significance, and points to metabolic derangement as a natural prelude to cancer.

Although Windaus and Wieland had seemingly settled the structure of the sterols, in 1932 Rosenheim and King, guided by the results of X-ray crystallography and by an observation of Diels, suggested an improved formulation. Since then organic chemists have not looked back, and the story of the elucidation of the structures of the sterols, bile-acids and sex-hormones forms the most fascinating part of the book. The cardiac poisons and the saponins are yielding their secrets too, and are already known to possess the same polynuclear system as the sterols, which has the most diverse distribution in Nature, and may fulfil the most manifold functions. Structures chemically similar have such different physiological properties as those of vitamin D, the sex-hormones, and the cardiac poisons!

The book may be recommended to all chemists interested in the subject; the author, who has himself made worthy contributions, deals impartially with the work of many investigators in many lands, and frequently interpolates his own valuable suggestions where finality is still lacking.

(3) This text-book presents organic chemistry in a way making for closer liaison between theory and laboratory practice, but is recommended also as a reference book, not least for the large number of well-chosen references. Compounds are treated according to functional groups in eleven chapters, each of which has a summary and descriptive tables; reactions are dealt with fully, and a number of representative preparations is included.

Within the limits imposed by the author (for example, heterocyclic compounds and condensed nuclei are only referred to incidentally) the work is reasonably complete. The section on diazonium compounds might have included Nesmejanov's work on mercurials, and that on halogen compounds recent patent literature on sodium alkyls and aryls. On the other hand, the influence of structural factors, polar or steric, on the course of well-known reactions is usefully treated.

With journals so drastically abridged that reactions are referred to only by the names of their discoverers, the author might have named them so; and the absence of an author index makes it difficult to look up less-known reactions. Textual errors are rare, and generally of a minor nature. For the amount of information it contains, the book is low priced, and should prove invaluable to the student as a manual of organic reactions, and an aid in the identification of carbon compounds.

Mysore Tribes and Castes

The Mysore Tribes and Castes
By Diwan Bahadur L. K. Ananthakrishna Iyer. (Published under the auspices of the Mysore University.) Vol. 1. Pp. lxxii + 502 + 68 plates. (Mysore: Government Oriental Library, 1935.) 15 rupees; 24*s*.

A PERIOD of more than thirty years has elapsed since the late Mr. Nanjundayya commenced a systematic survey of the tribes and castes of Mysore on the lines laid down by a former Census Commissioner for India, the late Sir Herbert Risley. In 1925, Mr. Ananthakrishna Iyer succeeded the original superintendent of the Mysore Survey. Three volumes have already appeared containing the Survey results, caste by caste, in alphabetical order; and we now welcome the appearance of vol. 1, which deals with the results as a whole.

It is not unusual for the authors of such works to invite a distinguished scholar to add a short introduction to his general volume; but Mr. Ananthakrishna has thought fit to enlist for this purpose the assistance of several well-known anthropologists, so that his book becomes more a compendium of essays than the mature conclusions of one writer. Thus, Dr. R. R. Marett commences with a short appreciation of the book, and some interesting reflections on the parts which East and West may profitably play in such inquiries. The late distinguished scholar, M. Sylvain Lévi, follows with some general remarks on the nature of caste. These are followed by a translation for use in India.

We then come to a lengthy and most important essay by Baron von Eickstedt, of Breslau. This is perhaps the most important feature of the book. Von Eickstedt, dealing in some detail with the racial invasions of India in the past, and after allotting due influence to occupation and environment, presents the reader with an entirely novel classification of the population, for which he supplies some anthropometrical data. It will be remembered that most former writers on Indian racial elements have been disposed to assume an original Kolarian population of a very early type, displaced later, largely in the south, by a Dravidian immigration, upon which followed the arrival from the north-west passes of an Aryan-speaking people. Later bands of immigrants, such as the Scythians, Yuechi, and Huns, penetrated northern and western India between 100 B.C. and A.D. 600. Von Eickstedt, rejecting the existing terminology as savouring too much of linguistic instead of racial significance, evolves a threefold base for the Mysore population, namely, the Veddids, the Melanids, and the Indids. To each of these he allots sub-groups. A table giving anthropometric data for these will be found on p. 76.

The reader must be left to study for himself the exact significance of these new divisions. It is possible to convey a rough idea of them by explaining that the Veddids have much in common with the old Kolarian, the Melanids seem to be similar to Dravidian, and there is little to distinguish the Indid from the Aryan. In the special Ethnographic Appendix to the last Census of India, some doubt is thrown on the value of von Eickstedt's classification owing to the inadequacy of the anthropometric data on which it rests. It is, however, one that will repay careful examination; and it certainly possesses the merit of simplicity when compared with the almost incomprehensible formulæ of 'co-efficients of relative likeness' on which Dr. Guha proceeds in the Census of India volume.

Not content with the assistance of the three scholars referred to above, the compiler of this volume next offers the reader a chapter on the cultural geography of Mysore by a distinguished member of the Indian Civil Service, Mr. F. J. Richards. Writing with personal knowledge of the country, Mr. Richards gives us a thoughtful study of the history and cultural features of the population of Mysore which by itself would make Mr. Ananthakrishna's book a valuable possession. Interesting charts are added, showing the extent and distribution of various elements in the population, such as Marāthas Lingāyats and Jains. From these it can be learned by a rapid glance how the main castes and tribes are distributed throughout the State territories.

Following these more or less introductory essays, the reader will find chapters on caste, religion, taste in dress and ornaments, totemism, magic, animism, etc.; and here we meet for the first time with an attempted summary of the various contents of the articles in the preceding volumes. The writer's survey takes him far afield; and we are even given specimens of the particular tattoo marks favoured by Hindu ladies, such as a picture of the temple of the god Shiva, accompanied by his attendant *Nandibail* (p. 438). Space does not, unfortunately, admit of a study of the significance of this material. A few words must, however, be devoted to the important Chapter vii, which deals with the practice of totemism.

Some recent investigations in the neighbouring Presidency of Bombay concerned with the same subject have tended to show that more prospect exists of arriving at the origin of the population by having regard to the practices of the people in this connexion rather than by measuring their heads and their noses. In the pages of the *Indian Antiquary* (61, 106–111; 1932) a list of some two hundred and twenty totem divisions identified in the centre and south of the Bombay Presidency will be found, and will repay most careful study. On p. 255, Mr. Ananthakrishna gives a list of a hundred and twenty-five such totems, which are classified as animals, trees and plants, and inanimate objects. Needless to say, the resemblance to the Bombay list is striking, the entries in many cases being identical. As was to be expected, the author of this work finds the system in many cases to be in a state of decadence; but it is none the less widespread among tribes and castes of non-Aryan origin. He shows that customs such as matriarchy, adult marriage, burial and totemism are a surer guide to the racial origin of a caste or tribe than most of the traditional accounts which are so readily forthcoming to mislead the investigator.

The chapters on animism and magic contain little that has not already been recorded in other works on the subject. On p. 237 *et seq.* reference is made to the curious custom known as the *couvade*. Mr. Rice, in the *Mysore Gazetteer*, has already supplied evidence of confinement restrictions on the husband among the Kuravas. Little fresh material can be gathered from the present volume.

In conclusion, it remains to congratulate Mr. Ananthakrishna Iyer on the completion of his great task. The separate and final volume promised by him, which is to contain a bibliography and index, will be awaited in the hope that it may also find place for the missing synonyms of caste and tribal names which the previous three volumes should have included. The present work is signally free from misprints, though it may be observed that 'ironette' (p. 473) as a kind of dancing seems a somewhat novel form of movement. Are we really dealing with a 'pirouette'? There are numerous excellent illustrations.

R. E. ENTHOVEN.

The Land of Britain:

the Report of the Land Utilisation Survey of Britain. Edited by Dr. L. Dudley Stamp. Part 78: Berkshire. By J. Stephenson, with an Historical Section by W. G. East. Pp. 113. (London: London Utilisation Survey of Britain, 1936.) 2*s.* 6*d.*

THE publication of the first of the contemplated eighty-seven county reports on the utilization of the land of Great Britain gives an idea of the scope and value of the work. The report begins with a summary of the geographical background, geology, relief, soils and climate. Then follow accounts of the distribution of woodland, arable land and grassland, which are closely correlated with physical conditions and illustrated with distributional maps. Next comes the distribution of orchards and poultry farming and lastly the distribution of settlements and population in general.

The report brings out not merely the present use of the land but also indicates the changes that have taken place chiefly through the operation of economic factors. Thus to-day the arable land of Berkshire covers 26·5 per cent of the county, while in 1808, and for many years subsequent, it appears to have covered more than fifty per cent. The process of putting arable land down to grass is still continuing. On the other hand, arable farming would appear to be concentrating in the areas best suited to that use. This tendency is accentuated by better transport, which helps to nullify advantage of position, and uniform wages which reduce the ability of poor areas with low wages to compete with better land. Mr. Stephenson concludes by dividing the county into agricultural regions each with its own characteristics and potentialities, and he notes that Berkshire is in a transitional stage common to all counties near London. Price conditions are changing the aspects of farming, and growth of population and transport are making the east and south more and more into residential areas.

The report concludes with a valuable article by Mr. W. G. East on the utilization of the land about 1800.

Wild Flowers of the Wayside and Woodland

Compiled by T. H. Scott and W. J. Stokoe, based upon the Standard Work "Wayside and Woodland Blossoms" by Edward Step. Pp. 352+81 plates. (London and New York: Frederick Warne and Co., Ltd., 1936.) 7*s.* 6*d.* net.

THIS attractive book will prove very useful to the field naturalist rather than to the academic student of systematics. It is well produced, and is of a size convenient for the pocket. Such a book, well printed and beautifully illustrated, is just that type which helps the intelligent man to a truer appreciation of the country, while at the same time giving a valuable insight into the beauties of Nature. It should, therefore, give full satisfaction to the country rambler interested, if only mildly, in the surrounding flora. Apart from this, however, it will provide an excellent introduction to a later more serious study of systematic botany.

The book opens with a short description of the more common forms of leaves, and this is illustrated by two pages of line diagrams. Next follows a short dissertation on the forms of flowers, illustrated by a typical flower and line diagrams of the more common types of inflorescences. A short glossary of botanical terms helps the reader to follow more easily the descriptions in the greater part of the book.

An unusual and helpful feature then follows: forty pages are devoted to line diagrams of common flowers, grouped according to the colours, white or whitish, and shades of pink, red, yellow, blue, purple, lilac, green and brown.

The bulk of the book is occupied by a description of the most common plants in the British flora. This occupies about 250 pages, interspersed with eighty coloured plates each portraying about four types of flowers. There is an index.

This book is to be unreservedly recommended, and, in view of the amount of subject matter and coloured illustrations which it contains, it is excellent value for the price demanded.

The Heavens and Faith

By the Rev. M. Davidson. Pp. xv+162. (London: Watts and Co., 1936.) 5*s.* net.

THE impact of the science of astronomy upon the Christian faith is a topic which has been dealt with by a number of writers, but Dr. Davidson is better equipped than many, because he is at once a clergyman and an astronomer, Sir Frank Dyson testifying in a foreword to his competence in this science. But, what is not less important, Dr. Davidson has not only the requisite knowledge, but also the necessary candour, apart from which all discussion ends with foregone conclusions.

The problems set for religious faith by modern astronomy are threefold: (1) the apparent indifference of an incredibly vast universe to man and his destiny; (2) how to reconcile the three-storey universe of Creeds and Scripture with present scientific knowledge; and finally (3) what we are to make of the eschatological beliefs entertained not only by Paul and the primitive Church, but also, as is now recognized by scholars, by the Founder of Christianity himself. Most works of orthodox apologetic tackle (1) and (2) with varying degrees of success, but there is a widespread tendency to ignore (3) altogether, in spite of its vital importance. Dr. Davidson, however, does not evade this issue, nor seek to obscure the point that the ethic of the Sermon on the Mount had a very definite basis of apocalyptic belief which is no longer held. How far its validity may be thereby affected is a matter for serious inquiry and not for dogmatic assertions. As a matter of fact, if we believe that the world is soon to end and be replaced by a better, the ethic of the Sermon is mere common-sense, and not fantastic idealism, as it appears to most 'world-accepting' citizens to-day.

This book was very well worth writing, and will repay study. J. C. H.

Out of the Night:

a Biologist's View of the Future. By Prof. H. J. Muller. Pp. 127. (New York: The Vanguard Press, 1935.) 1.50 dollars. Pp. 160. (London: Victor Gollancz, Ltd., 1936.) 4*s*. 6*d*. net.

EUGENICS is based very largely on genetics, and any technical or theoretical advance in the latter science has its effect on eugenical thought. Consequently, the considered views of Prof. Muller, well known as one of the leading geneticists of the day, on eugenical topics are very welcome.

Prof. Muller commences with a consideration of the evolution of man, illustrating his argument with novel and effective analogy. He then discusses the future of man and contrasts man's probable fate if conscious control of the occurrence of various genetical types is not exercised, with his possible achievements if such a control is successfully attempted.

The author next considers the measures which seem desirable for the purpose of such a control of genetical change in man. He favours the extensive use of a few chosen sires, by a technique involving the storage of gametes and artificial insemination. It is important to note that technically many of the proposals made are either possible at present or likely to be rendered possible by a relatively small amount of further research.

It is certain that Prof. Muller's views on the technique of human improvement will not be universally accepted. Some geneticists do not agree that the use of a few chosen sires is the best way of achieving rapid selection. It can be stated, however, that, in spite of possible disagreement on some points, the book will be of great interest to anyone concerned with the problems of eugenics, as it is both genetically and technically accurate.

K. MATHER.

L'Année psychologique

Fondateurs: Henry Beaunis et Alfred Binet. Publiée par Prof. Henri Piéron. (Bibliothèque de Philosophie contemporaine.) Année 35 (1934). Vol. 1. Pp. xix+480. Vol. 2. Pp. 481–912. (Paris: Félix Alcan, 1935.) 120 francs.

THIS excellent annual publication becomes more and more an indispensable aid to the study of the ever-increasing production of works and memoirs on psychology. The research value of the "Année Psychologique" is shown not only in its original memoirs, but also and mainly in the useful classification and summary reviews of the current literature concerning psychology published during the year. Among the original memoirs published in the present issue, we should mention H. Piéron's "L'Evanouissement de la sensation lumineuse" and the two essays on psychological factors by N. Margineanu. The classification of the works reviewed occupies fourteen pages of the table of contents; which shows the reviewer's difficulty in making a satisfactory selection, and also the wealth of material which has been sifted and analysed by the editors of this important publication.

T. G.

The Monks of Athos

By Prof. R. M. Dawkins. Pp. 408+6 plates. (London: George Allen and Unwin, Ltd., 1936.) 15*s*. net.

PROF. DAWKINS, whose knowledge of the eastern Mediterranean now extends over more than thirty years, has long been known to students not only as an archæologist, but also as a diligent collector of the folk-lore and legends current, or recently current, among the modern Greeks of the mainland and the islands. In the course of four visits to Athos, he has made a gathering of the legends current among the members of the remarkable monastic communities of the peninsula, to which he has added a gleaning from the literature relating to it. His purpose, however, has been inspired by a deeper motive than that of collection merely: his aim has been to test the value of folk-memory as preserved in these legends—a purpose for which Athos is better fitted than most localities. It is somewhat remarkable to find that, in communities which are notoriously anti-feminine, the Virgin Mary holds a place no less prominent than in other parts of the Mediterranean. It is also to be noted, the author points out, that theological controversy, which has raged here on more than one occasion, appears to have been forgotten almost immediately after settlement, and has left little or no mark on tradition.

Prof. Dawkins found that his main purpose would have been very inadequately served without some account of the geographical and cultural setting. In consequence, he has written a full description of the peninsula, which conveys its charm in a literary style no less felicitous than the subject matter demands.

Geologie von Asien

Von Prof. Dr. Kurt Leuchs. Band 1, Teil 1: Überblick über Asien, Nordasien. (Geologie der Erde, herausgegeben von Prof. Dr. Erich Krenkel.) Pp. viii+236. (Berlin: Gebrüder Borntraeger, 1935.) 18.40 gold marks.

THIS addition to the "Geologie der Erde" series, published under the general editorship of Prof. E. Krenkel, is planned to comprise two volumes each of two parts, and, in its completed form, will fill a long-felt want in geological literature.

The first part of vol. 1 contains a general introduction including a summary of the physiography and geological structure of Asia as a whole. This is followed by the section dealing with north Asia, which includes a relatively detailed discussion of the stratigraphy and igneous rocks, the tectonic structure and the chief ore deposits of the region.

To some extent it covers the same ground as Obrutschew's "Geologie von Sibirien", published in 1926; but in the intervening years much new material has become available and is incorporated by Prof. Leuchs.

The chief value of this book lies undoubtedly in the fact that it summarizes and makes available a great body of obscure, and for all practical purposes, inaccessible Russian publications, and as such is a notable addition to geological literature.

Seventh International Congress of Refrigeration

By Dr. Ezer Griffiths, F.R.S.

THE Seventh International Congress of Refrigeration, organized by L'Institut International du Froid and the Netherlands Association of Refrigeration, opened at The Hague on June 16 and closed at Amsterdam on June 20. For the opening ceremony, about four hundred members of the Congress, including delegates of fifty nations and members of the Dutch Government, assembled at the historic Ridderzaal—the Hall of the Knights at The Hague. At this meeting, speeches of welcome were made by representatives of the Dutch Government and such preliminaries settled as the appointment of presidents and secretaries of sections, together with the procedure to be followed in the conduct of the meetings.

The work of the Congress was subdivided between four sections, and altogether about two hundred papers and reports came under consideration. Abstracts of the papers were printed in the language supplied, followed by translations in French and (or) English. The topics of these papers covered the whole field of low temperature work, and were of a varied character, ranging from paramagnetism to a new method of making ice rinks. The mass of material to be dealt with proved embarrassing, since in the limited time available full discussion was impossible.

There was a feeling that a more rigid process of selection would need to be followed in preparing the programme of the next Congress. In a congress of this character, adequate time for discussion is all-important, for sometimes ancillary information of considerable interest is brought out in the course of a discussion. For example, a paper was read describing the development of refrigeration in Japan ; and, in answer to a question, an outline was given of the method employed in certain parts of that country for the cultivation of strawberries—a subject of general interest. A sunny slope is selected exposed to sea-breezes. The rocks are arranged with pockets of earth between, and in these the roots of the strawberry plant are planted. At night the rocks cool and condense water vapour which trickles down the rocks and is absorbed by the earth. By day the rocks warm up rapidly and afford a source of heat to the strawberry plant.

The majority of the papers dealt with that aspect of low temperature work which is concerned with methods for the preservation of perishable foodstuffs. The papers read at this Congress would perhaps suggest that the engineer is greatly in advance of the biologist in the science of refrigeration, but this impression is probably due to the fact that biological workers as a whole failed to support the Congress to the same degree as their engineering colleagues. Much of the biological work recorded was more of a descriptive character than an attempt to get down to fundamentals as regards the chemical and structural changes taking place consequent on storage temperature and environments. There is great scope for investigation on the biological side, particularly in respect of tropical fruits, and it may be of interest to record that a resolution was passed at this Congress recommending that the question of tropical fruits should occupy a prominent place in the programme of the next Congress ; such fruits afford interesting material for research, for it is possible to carry out, in the course of weeks, experiments which may be protracted over many months in the case of hard fruits.

Reverting to the engineering side, it was noteworthy from the papers submitted to the Congress that advances are being made in the production of temperatures considerably lower than those customary in cold-stores work, although of course much higher than liquid air temperatures. Here the question is not one of the mere attainment of low temperatures, but the economical production of temperatures of the order of − 50° C. in large spaces. For example, ice-cream manufacturers prefer quick hardening of their product in wind tunnels at − 40° to − 50° C. to slow hardening at a higher temperature.

These developments in refrigeration have resulted in the evolution of special types of refrigerating machinery. For intermediate temperatures of, say, − 25° to − 40° C. the booster compressor of the rotary blower or piston type finds application in raising the pressure of low density vapour to densities at which it can be efficiently handled by compressors of standard design. Lower temperatures are obtainable by refrigerating equipment of the modern absorption type, in which temperatures so low as − 76° C. can be economically obtained in commercial practice, using ammonia, in spite of that temperature being within one degree of the triple point of ammonia and the specific volume being twenty-five to thirty times as great as at ice-making temperatures.

The question may reasonably be asked what useful purpose does such a Congress serve. In the first place, it affords unique opportunity for workers in various countries to establish contact and exchange views, and on this occasion the various nationalities came together with a common objective. Representatives from the Dominions Overseas appreciated to the full the value of the Congress as an opportunity to meet their colleagues. The Congress also demonstrated to those countries which are lagging behind in the encouragement of scientific work the benefits accruing from organized research.

During the period of the Congress, meetings of some of the commissions functioning under the auspices of the Institut International du Froid were convened. Commission No. 1 considered the question of temperature measurements down to liquid hydrogen temperatures. The temperature scale is defined by international agreement down to the boiling point of oxygen; beyond this there is no generally accepted standard scale. Even in the range covered by the International Scale, further work appears to be necessary, since some investigators have found that platinum thermometers constructed and calibrated according to specification differ by so much as 0·03° at about – 140° C. To study this question, it was decided to set up a committee composed of representatives of the various national laboratories and of those centres where low temperature investigations are in progress.

Commission No. 12 on land transport and Commission No. 13 on water transport held a joint session. As problems for further study, they decided that data should be collected as to the heat production of various types of fruit, this being a matter of interest to the marine engineer when dealing with fruit delivered to the ship without pre-cooling. It was also decided to consider methods for the control of the atmospheric conditions in the holds of ships carrying perishable produce requiring atmospheres of high carbon dioxide and low oxygen content.

These are subjects which will be studied by expert committees under the auspices of the Institut International du Froid and reported upon at the next Congress.

Thanks to the thorough planning of the executive committee, the arrangements worked smoothly and efficiently, and those participating will retain the most pleasant memories of a very useful meeting.

The Royal Research Ship *Research*

By Dr. H. Spencer Jones, F.R.S., Astronomer Royal

THE destruction of the non-magnetic ship *Carnegie* by an explosion, at Apia, Western Samoa, on November 29, 1929, brought to a sudden end the magnetic survey of the oceanic areas, which had been carried on for twenty-five years by the Carnegie Institution of Washington. The *Carnegie* had been specially designed and constructed for obtaining magnetic observations at sea. She was a hermaphrodite brig, built of white oak and pine, with copper or bronze fastenings, and with a displacement of 568 tons. She was equipped with an auxiliary engine, capable of giving a speed of about 6 knots in calm weather; the engine was of internal combustion type and, at first, used gas generated from solid fuel, but, as this proved not altogether satisfactory, petrol was substituted. Sufficient fuel was carried to give a cruising range of 2,000 miles at 6 knots. With the exception of cast-iron pistons for the cylinders of the engine and the steel cams necessary for operating the valves, amounting in all to less than 600 lb., no magnetic material was used in the construction of the ship.

In six cruises between 1909 and 1921, the *Carnegie* traversed 252,702 miles in 3,267 days actually at sea. Her last cruise was planned to extend from May 1928 to September 1931 and to cover 110,000 miles. It was designed to determine the secular change of the earth's magnetism in all oceans, by making numerous intersections with the tracks of previous cruises. Nearly one half of this cruise had been completed at the time of her loss.

The results obtained by the *Carnegie* were placed freely and promptly by the Carnegie Institution at the disposal of the British and other Governments, for use in the construction of world magnetic charts. Successive issues of these charts were based to an increasing extent upon the data provided by the *Carnegie*.

The secular changes of the magnetic elements at any given place are not constant quantities. Extrapolation over long periods may therefore lead to considerable errors. The continual accumulation of observations is necessary in order to determine both the secular change and the rate of change of the secular change of each element. At the present time, the magnetic data are most uncertain in the Indian Ocean. The last cruise of the *Carnegie* in the Indian Ocean was in the year 1919. The cruise on which she was engaged at the time of her destruction was to have taken her into the Indian Ocean in 1930 and 1931. In South Africa there has been a considerable decrease within recent years in the secular change of the magnetic declination, and in Western Australia there has been a considerable increase. There are no data available as to how the secular change is altering in the southern Indian Ocean between South Africa and Australia. The magnetic charts for this area are therefore based at present upon very uncertain extrapolations. In other areas, where the magnetic elements are known at present with reasonable accuracy, the extrapolated values would become less and less reliable in the course of time, in the absence of further observations, such as were provided by the *Carnegie*, to serve as a control on the changes in the secular variations.

In view of the fact that Great Britain is the principal maritime nation, the British Government has accepted the responsibility of providing accurate magnetic data at sea, and a non-magnetic ship is to be built, equipped and operated for this purpose by the Admiralty. The ship is to be known as the Royal Research Ship *Research* (R.R.S. *Research*), and she will fly the Blue Ensign and Jack with the yellow Admiralty anchor in the fly.

The plans for the new ship have been prepared at the Admiralty and it is hoped that the construction will be commenced shortly. The Department of Terrestrial Magnetism of the Carnegie Institution of Washington not only placed at the disposal of the Admiralty all information with regard to the construction and the instrumental and other equipment of the *Carnegie*, but also generously gave the services of Mr. W. J. Peters as consultant, without charge. The experience and advice of Mr. Peters, who commanded the *Carnegie* on her first two cruises, have been of the greatest value in the design of the ship and of her equipment.

The R.R.S. *Research* will be somewhat larger than the *Carnegie*. She will have a displacement of 650 tons and will be brigantine rigged. She will be provided with a single screw Diesel engine and will carry sufficient oil fuel to give a radius of action of about 2,000 miles at 6 knots. Her cables will be of bronze, instead of the hemp rope used in the *Carnegie*, and to some extent brass or bronze will take the place of wood. She will carry a total complement of 31, including the commanding officer, three deck officers, three scientific workers, a surgeon (who will also be a scientist) and an engineer.

The work of the R.R.S. *Research* will not be restricted solely to magnetic observations. She will undertake observations of atmospheric electricity. Such observations are particularly valuable at sea, where the air is less contaminated by suspended impurity than it is on land. It may be recalled that it was by means of observations on the *Carnegie* that it was established that the maximum potential gradients are related to Universal Time and not to the local time of the place of observation. The *Research* will be provided with an oceanographic winch and motor for oceanographic work, will carry an echo depth sounding gear, and will also make meteorological observations, including upper air observations by means of pilot balloons.

The principal magnetic instruments for observations at sea will be a marine collimating compass for observations of declination ; a sea-deflector, for observations of the horizontal intensity ; and a marine dip inductor for observation of the dip. The collimating compass is a modification of the standard marine liquid compass. The magnet system carries four concave speculum mirrors, adjusted so that their optical axes are in the direction of the four cardinal compass points. A scale is mounted in the focus of each mirror. The four scales are carried on arms attached to the magnet system. The angle between the sun, when at low altitude, and one or other of the four compass points, as defined by the scale images, is measured with a sextant, the scales being viewed through windows in the compass bowl. This observation provides the means of calculating the magnetic declination. The compass will be mounted in such a position that it will have as clear a view of the horizon as possible.

The sea deflector consists of a marine compass, provided with permanent attachments, whereby a deflecting magnet can be mounted in a horizontal position and vertically above or below the compass magnet system. The bowl is rotated until the deflecting magnet is perpendicular to the compass magnet, as shown by the reading of the card. The angle of deflection is read on a graduated scale on the edge of the bowl. The deflector is mounted in an observatory adjacent to, and forward from, the chart room, in which is the standard compass. As the observer at the deflector reads off the angle of deflection, a second observer at the standard compass reads off the direction of the ship's head. The horizontal intensity is proportional to the cosecant of the deflection. The constant of proportionality is determined periodically by simultaneous observations ashore, with the sea deflector and land magnetometer.

The marine earth-inductor follows the general design of earth-inductors, but is provided with a special gimbal stand that is not affected by the rotation of the coils. It is important, for observations at sea, that it should be driven at a constant speed, and a special tuning-fork controlled rotary converter, situated in the after part of the vessel and driving through an articulated phosphor-bronze shaft, will be provided to ensure this. Two galvanometers, one of the moving coil type, with short period, and the other of the string type will be provided and experience will be gained at sea of the relative suitabilities of the two types. The earth-inductor will be mounted in an after observatory.

Portable instruments for land observations, at fixed magnetic observatories and elsewhere, will also be carried. The designs of the instruments have been based on the Carnegie Institution designs, with such modifications as were suggested by experience on the *Carnegie* or as seemed desirable for various reasons.

The magnetic observations on the R.R.S. *Research* will be made primarily in the interests of navigation. But they will provide at the same time valuable information about the earth's magnetism, which is needed for the investigation of such matters as the non-potential portion of the earth's field and the line integrals around closed contours on the earth's surface.

Body Orientation of the Lower Crustacea (Branchiopoda)

By John H. Lochhead, University Museum of Zoology, Cambridge

AMONG the Branchiopoda it is now well known that the Anostraca swim normally lying on the back, while the Notostraca swim with the back directed upwards. Orientation is also constant among the Cladocera, but there are here considerable differences between genera.

Four possible controlling factors have been suggested. These are the aeration of the water, gravity, the surface resistance of the animal, and light.

Lowndes[1] and Wertheim[2] hold that the limbs of Anostraca, which are doubtless respiratory, are normally directed upwards because the upper layers of water are best aerated. This view, however, cannot apply to the Notostraca. Nor could orientation be controlled in this way except perhaps very near the water surface, since the differences in aeration above and below a swimming animal must normally be too small to be detected. It is true, however, that both Anostraca and Notostraca often come up and beat their limbs just below the surface film, the Notostraca specially turning over on to their backs for this purpose. It has been widely stated that this occurs especially when the oxygen content of the water is low. It may thus well be a respiratory phenomenon, though Mathias[3] has shown that the oxygen requirements of *Artemia* are surprisingly small. In any event, however, the habit is quite distinct from the more usual swimming of the animals farther below the surface.

Control of orientation by gravity may occur in two ways. There may be automatic control, the centre of gravity of the animal being so placed that a constant attitude tends to be maintained independent of muscular effort. The factor of the resistance offered by the surface shape of the animal to the water may also play a part here. Or there may be nervous control due to the effect of gravity on special sense receptors, the position maintained by the animal being then not necessarily the stable one with respect to the automatic forces just mentioned.

Surface resistance is a factor of special importance in the Cladocera, because of the regular rest pauses which characterize their swimming. But in the Anostraca and Notostraca, considered for the sake of simplicity only when swimming or floating more or less horizontally, the effect of surface resistance on dorso-ventral orientation must be small. R. T. Müller[4], however, has shown that for Anostraca the effect due to the centre of gravity may be important. It has long been known that in water the anostracan body sinks back downwards. This might be due to the position of the centre of gravity, or to surface resistance. Müller showed that it is due to both these factors. He placed both fixed and narcotized *Tanymastix* in sugar solution of the same specific gravity as that of the animals, and found that they then lay floating in the solution back downwards. This could be due only to the position of the centre of gravity. He then raised the specific gravity of the solution until the animals rose up fairly rapidly towards the surface; they did so back upwards, surface resistance overcoming the force exerted by the centre of gravity. Thus when an anostracan sinks in water, both forces tend to keep the back downwards. For the Notostraca, such careful experiments have not been done; but Seifert[5] has shown that a dead *Apus* also sinks in water back downwards. Probably this is due to the same forces acting together as in the Anostraca. If this is so, then *Apus* normally swims in an unstable position with respect to its centre of gravity, and if gravity plays any role in controlling orientation it must be by acting on sense receptors. But although *Apus* has been histologically well investigated, nothing in the nature of a statocyst has been found.

The effect of light on the dorso-ventral orientation of Anostraca and Notostraca may be very marked. But Müller[4] gives much experimental evidence to show that in the anostracan, *Tanymastix*, the responses occur only when phototropism has been awakened by other stimuli ; the possibility that this may also be the case for the Notostraca has not been investigated. Both orders, however, respond to sudden changes in the direction of light, the Anostraca seeming always to try to keep the ventral surface facing the source of light, while Notostraca show the opposite response. This corresponds with the normal swimming positions of these animals when light is coming from above. When illuminated from below the animals turn over, though the fresh-water Anostraca seem to find difficulty in swimming in the unaccustomed and unstable position. Individuals of *Streptocephalus* observed by me repeatedly 'looped the loop' when illuminated from below, swimming slowly ventral side down when at the bottom of the loop and going rapidly, ventral side up, over the top of the loop. *Apus* when illuminated from below swims easily on the back, this being for it, as it is for the Anostraca, the presumably stable position with respect to the centre of gravity. In both Anostraca and Notostraca, control of orientation in respect to light has been shown by Seifert to be effected in the first place solely through the eyes. In the Anostraca he has shown[6] that probably only the lateral eyes are concerned. In the Notostraca he has found[6] the lateral eyes to play the chief part, assisted, however, to a small extent by the median eye.

It may be concluded that, while in fresh-water Anostraca control of orientation by light is probably secondary to that exerted by the centre of gravity, this is apparently not so for the Notostraca. Here the normal swimming position is perhaps in direct response to the direction of light, although the possibility that gravity plays a role is not excluded. Seifert[5] found that *Apus*, in response to a change in the lighting, appeared to turn over more rapidly to the normal position with the back upwards than it did for the reverse change. He also found that when the normal habitat conditions are reversed, by lighting from below and placing a false bottom above, *Apus* does not behave towards this false bottom in the same way that it does towards a true one when the light comes from above. But the tendency for the animal to sink rather spoils the significance of this experiment. Much more interesting should be the behaviour of the animals at night. I have found, in agreement with Müller, that fresh-water Anostraca continue to swim ventral side up at night, this being the stable position with respect to the centre of gravity. But for the Notostraca I have no observations on this point, and I can find only two brief notes by Seifert[5]. He states (p. 403) that animals swimming in the dark show some uncertainty in their orientation, and (p. 414) when allowing themselves to sink down after a period of swimming, do so back downwards. These observations, if they are correct, would seem to show that it is indeed light which controls the normal daytime swimming position of the Notostraca. In fresh-water Anostraca this control is probably more latent, being awakened, according to Müller, only by certain disturbing stimuli.

An interesting confirmation of the probable truth of these general conclusions is contained in the later paper by Seifert[6]. In this paper, Seifert compares a fresh-water anostracan, *Chirocephalus*, with the 'brine-shrimp', *Artemia*. For *Chirocephalus* his results are in close agreement with those of Müller on *Tanymastix*. But he finds that in *Artemia* conditions have been reversed by the nature of the environment. *Artemia* swims on the back like other Anostraca, but Seifert finds that in the strong brine in which it lives, this is actually the unstable position, because its body is tending to rise rather than to sink. Correlated with this presumed instability of the normal swimming position, there is a much more constant orientation of the body with respect to light than has been found in other Anostraca. Probably Seifert would thus divide the Euphyllopoda into those forms which normally swim in a 'stable' position and respond to light only after suitable stimulation, and those forms which swim in an 'unstable' position, maintaining their orientation by a constant response to the direction of light.

Clearly other factors than light and gravity, such for example as the currents set up by the animal, may also play a part. But for the sake of simplicity I have not considered these here ; nor have I more than briefly mentioned the Cladocera, because the large amount of work done on this group has already been well reviewed (*cf.* Wagler[7]).

Obituary

Mr. A. H. S. Lucas

AUSTRALIAN science loses a notable and versatile votary by the death of Arthur Henry Shakespeare Lucas, on June 9. The son of the Rev. S. Lucas, he was born in 1853 at Stratford-on-Avon and educated at Kingswood School, Bath, and the University of Oxford, where he was an exhibitioner of Balliol College.

Going to Australia as mathematics and science master of Wesley College, Melbourne, in 1883, Lucas later became tutor and natural science lecturer at Trinity, Ormond and Queen's Colleges of the University of Melbourne. From 1893 until 1898 he was headmaster of Newington College, Sydney, after which he joined the Sydney Grammar School as mathematics and science master, and headmaster in 1920. He was also for some time lecturer in physiography at the University of Sydney. Retiring from school work at the end of 1923, he acted for two years as professor of mathematics at the University of Tasmania.

One of the founders of both the Victorian and the New South Wales Naturalists' Societies, Lucas was president of both at different times. In 1907–9 he was president of the Linnean Society of New South Wales, and he was a councillor until his death. For many years he was curator of the Algæ of the Sydney Botanic Gardens, and the last twelve years of his life was devoted to active research and wide collecting of Algæ, from Western Australia to the Barrier Reef, usually spending the summer months—including the last—with his co-adjutors, Mr. and Mrs. Perrin, near Georgetown, Tasmania, in this work. His last paper, "The Marine Algæ of Lord Howe Island", was read at the Linnean Society of New South Wales in June 1935. His "Introduction to Botany", written in conjunction with Prof. Dendy, is a well-known text-book to Australian students. But botany, although his chief love, was but one of many studies. In his teaching life, one learned that his personal pupils in the Senior Public Examinations had won University medals in eleven different subjects—these including all branches of science and mathematics. Besides papers on Australian lizards, in collaboration with the late Dudley Le Souef, he published two books on the animals and on the birds of Australia respectively.

Lucas's passion for acquiring learning led him also into the study of languages. A sound classic and English scholar, he extended his range of modern languages beyond the usual French and German to Italian, Spanish and Russian, by way of holiday pastime. The present writer, spending a summer vacation with him at Twofold Bay, found him reading "Don Quixote" in the original, while during the Great War he was requisitioned to interpret Russian in a law court, in the cause of some Russian refugees. Italian was a necessary concomitant to the study of De Toni's work on Algæ. Far beyond Dr. Johnson's conception of learning, Lucas earned the famous epitaph on Goldsmith "Nihil quod non tetigit; nihil tetigit quod non ornavit".

A great teacher, a humorous and lovable friend, Lucas's wide influence was attested by the large and representative gathering which—at the shortest notice—attended Roseville Church to pay the last honours to a rare personality. He leaves three daughters and three grandchildren. H. J. C.

Dr. J. D. Unwin

WE regret to record the death of Dr. J. D. Unwin, anthropologist and head of Cambridge House, the University social settlement in south London, which took place after an operation at the age of forty years.

Joseph Daniel Unwin was born on December 6, 1895, the son of Mr. F. D. Unwin of Chauntry House, Haverhill, Suffolk. He was educated at Shrewsbury School, and would have gone to Oriel College, Oxford, with a classical exhibition in 1914, had it not been for the outbreak of war. He served in the Northamptonshire Regiment and the Tank Corps, was twice wounded, and was awarded the Military Cross. After the War, he spent some years in Abyssinia. In 1928 he was elected a Fellow Commoner Research Student of Peterhouse, Cambridge. He then compiled a thesis in anthropology for the Ph.D., which was published in abbreviated form in 1933 under the title "Sexual Regulations and Cultural Behaviour". A fuller account of his research, with much additional material, was published as "Sex and Culture" in 1935. His theories of the relation of degrees or stages of culture and the intensity of sexual prohibitions, which was based upon evidence from no less than eighty tribes and peoples, attracted considerable attention and discussion. This book showed that Dr. Unwin had remarkable powers of analysing and marshalling cultural evidence. He had also engaged in research work for the Home Office on the subject of the imprisonment of debtors. The results of this research appeared in "Imprisonment for Debt" (1935). He also wrote "Notes on the Unwin Family" (1934).

Dr. Unwin's knowledge of social conditions and problems made his appointment as head of Cambridge House peculiarly suitable; and it was fully justified by his work for the settlement.

Miss Alice Balfour

MISS ALICE BLANCHE BALFOUR, of Whittingehame, who died on June 12, at the age of eighty-six years, was a naturalist born and bred, and her scientific interest in Nature persisted in spite of the social distractions of her association with her brother, Arthur James Balfour, politician and philosopher. In her earlier days, her bent was shared and encouraged by a younger brother, Prof. F. M. Balfour, already a leader in zoology when he died at the age of thirty-one years. Later she paid particular attention to gardening, so that the garden at Whittingehame became famous for its beauty, and to the collecting of a full series of the butterflies and moths of East Lothian. Her knowledge of the specific characters and local distribution of these and of other living things was thorough, and her inquiries brought her often to the Royal Scottish Museum in Edinburgh, to which she left her natural history collections.

It would be misinterpreting Miss Balfour's life to regard science as dominating her outlook, for her intellectual interests were wide, and her chief activities were social, in the broadest sense, and personal; but it may be said that the sustained pleasure of her life depended upon her love of Nature. J. R.

WE regret to announce the following deaths:

Prof. Franklin D. Barker, professor of zoology in Northwestern University, an authority on Trematodes, on July 10, aged fifty-eight years.

M. Louis Bleriot, who made the first flight across the English Channel from Baraques, near Calais, to Dover, on July 25, 1909, in a monoplane having a three-cylinder engine of 22–25 horse-power, on August 1, aged sixty-four years.

Lieut.-General Sir Alfred Keogh, G.C.V.O., G.C.B., director-general of the Army Medical Service 1904–10 and 1914–18, and Rector of the Imperial College of Science and Technology, 1910–22, aged seventy-nine years.

Prof. E. J. Nanson, emeritus professor of mathematics in the University of Melbourne, on July 1, aged eighty-five years.

Dr. F. J. F. Shaw, director of the Imperial Institute of Agricultural Research, Government of India, aged fifty years.

News and Views

Dr. E. J. Allen, C.B.E., F.R.S.

ON July 30, a special meeting of the Council of the Marine Biological Association of the United Kingdom was held in the rooms of the Royal Society in order to appoint Dr. Stanley Kemp, former director of the "Discovery" expeditions to the antarctic, secretary of the Association and director of the Marine Biological Association at Plymouth, the appointment to take effect on October 1. The present director of the Station, Dr. E. J. Allen, retires at his own request on September 30 after forty-two years of arduous service to the Association. During this period, Dr. Allen has seen the Station grow from being a small and poorly equipped second-rate institution to becoming the premier marine biological station of the world. We propose to refer in a later issue to Dr. Allen's great services to zoological science.

Dr. Stanley Kemp, F.R.S.

DR. STANLEY KEMP is probably the leading authority on oceanography at present living. During the years which he spent cruising in the Antarctic, he finally elucidated the circulation of the water in that ocean and proved its bearing on the habits and life-histories of the various species of whale which go south during the brief Antarctic summer in order to feed and grow fat and during this period fall a prey to whalers. He discovered the amazing fact that the largest of them all, the Southern Fin-Whale, feeds practically exclusively on one small species of 'shrimp' about 2 inches long. The baby whale when born is 20 feet long; it grows to a length of 50 feet during its first year, and attains its full size (100 feet long) in less than five years. He showed further that each antarctic summer is characterized by an enormous growth of diatoms on which these 'shrimps' feed and consequently a rich oxygenation of the sea-water due to photosynthesis. As this water flows north to the antarctic circle it sinks from the surface to an ultimate depth of about 600 fathoms and it takes approximately five years to reach the equator. The sequence of antarctic summers can be traced in the patches of oxygenated water which it contains, and the intensity of the oxygenation of each patch marks the degree of warmth of the corresponding summer. Dr. Kemp's appointment is therefore a happy augury for the future of Plymouth and for fishery science in general. It is becoming increasingly clear that the variations in British fisheries are connected with variations in intensity of a southward flow of arctic water carrying with it stupendous harvests of diatoms and shoals of the most sought-after edible fish. Oceanographic exploration based partly on Plymouth may be as fruitful in the endeavour to elucidate the life-histories of these fish as antarctic exploration has been in unravelling the life-history of the whale.

Archæological Investigations in Syria

SIR LEONARD WOOLLEY'S report on the work of the British Museum's archæological expedition to Sueidia, near Antioch, immediately before closing down work for the season (*The Times*, July 31) records the completion of excavation in the reserved area of the harbour site and the cutting of trial trenches on and around the hill station at Sabounia, two and a half miles inland. At the latter point, while the existence of a walled town at least as early as the Mycenæan age is established, the fall of the walls through the disintegration of the sandstone cliffs, on the edge of which they were erected, has effectually disposed of the possibility of profitable excavation. Here, however, a find of vessels of copper and implements of bronze and iron has afforded instructive evidence of agricultural practice in Syria in the Byzantine age. At Sheikh Yusuf al Gharib further evidence was afforded of the activity of the port in the second half of the fourth century B.C., in the form of merchants' magazines, which had been burned, but had preserved a detailed picture of trade. A lamp store was stocked with lamps of both the imported and the locally made varieties, lamp fillers and Syrian oil bottles copying Greek models, while the stock of painted Attic *aryballi* bore witness to a common origin in common characteristics which made it possible to trace a definite shipment by a single firm and to date it within a few years. Gold and silver beads and silver coins of Athens, copper ingots and loose quicksilver marked a jeweller's shop. Back to the ninth century this is the most important Greek colony so far excavated. The absence of evidence from the earlier Mycenæan age is to be attributed to the forces of Nature, which have washed away the earlier portions of the site. Yet there is a link in a local copy of a Mycenæan vase and a single sherd of fine hand-made burnished black ware, which alone would suggest an earlier date. Though no inscription has been found, it is suggested that this is the ancient Posidium, mentioned by Herodotus as founded before the Mycenæan age.

Bronze Age Burials in Scotland

A NUMBER of bronze age burials with some remarkable and unusual features, recently disclosed by building operations at Doonfoot, Ayr, and at Riccarton, Ferniegair, Lanarkshire, are described by Mr. Ludovic Mann in *The Scotsman* of July 20. At Doonfoot, no evidence of a cairn was discovered, but at Ferniegair, a structure of stone, of which the overground portion had been demolished, had covered a group of burials. Some eighty tons of loose stones, some water-rolled, formed an understructure in which horizontal layers of turf had filled the interstices and survived in the form of black carbonized matter. Both cemeteries have yielded pottery vessels of various types, assignable to successive phases of the bronze age and, therefore, pointing to an occupation covering a considerable period of time. The earliest form is a small squat hand-made food-vessel, with incised and impressed zonal ornament. Traces of carbonized cereal adhere to the interior. The bodies had been placed in the contracted position, looking toward the rising, or, in one instance, the setting sun, at Midsummer. Over one body at Ferniegair was sheeting made from the twisted and plaited stems of the Scottish moss, *Polytrichum commune*. Other examples of this textile material have been found at Mount Vernon, Glasgow, in a bronze age cairn near Stranraer, and a few weeks ago at Craignish, Argyll. Mr. Mann states that the dimensions of the stones of the tomb structures conform with an ancient linear measure, as do the interior dimensions of the chamber; and also that the position of the urn-fields, and other remains, ancient roads and tracks, conform, in a geometric convention, also based on a common unit. Both Doonfoot and Riccarton, adjoining burials containe large cinerary urns, with cremated remains, inverte over squared stone slabs. These overlie burials the earlier inhumation period. At Doonfoot thr burials were superimposed. A further find recorde is at Catacol, Lochranza, Arran, where a six-fo skeleton was found in the extended position in a lon narrow chamber, constructed of small side slabs an heavy roofing stones. An iron object was found wit the body.

The National Central Library

THE twelfth annual report of the National Centr Library refers to anxiety regarding the financi position of the Library due to inability to replac from any other source the £4,000 previously receive as an annual grant from the Carnegie United Kingdo Trust. Fortunately, the Treasury grant-in-aid ha been increased from £3,000 to £5,000 for a perio of five years from April 1, 1936, and as a result th Carnegie Trustees have renewed their previous annu grant for a similar period. The continuance of bot grants is conditional upon an increase in annu subscriptions from libraries by at least £2,000 b March 31, 1938. In consequence of the financia situation, expenditure on books has been only £2,33 but in addition to 3,110 volumes purchased, 5,45 volumes have been presented. The total number o volumes lent during the year was 118,288 and ther are now 158 outlier libraries containing 6,303,00 volumes from which 10,002 volumes were borrowed Reference is also made in the report to the extensio of the regional system to cover the counties o Cornwall, Devon, Dorset, Gloucester, Hampshire Oxford, Somerset and Wiltshire. When this syste is established, the whole of England and Wales wi be covered in eight regional systems, in addition t the London Borough libraries inter-lending system Volumes lent to university libraries increased by 9 to 2,506. The system was used by 53 universit libraries and 1,201 of the volumes were supplied b the National Central Library, 77 by foreign librarie and 1,228 by other university libraries, 80·52 pe cent of the inquiries being supplied. The book supplied consist mainly of highly specialized an expensive books, books out of print, foreign books back numbers of periodicals, or unpublished university theses.

National Research Council of Canada

THE eighteenth annual report of the National Research Council, Dominion of Canada, covers the activities of the Council in 1934–35. During the year, the Associate Committees on Aeronautical Research and on Trail Smelter Smoke were re-organized and three important conferences were held, one on problems of the honey industry, another to formulate a programme of cold-storage investigations, and the third to investigate the potato situation and the utilization of a surplus. The work at the laboratory for laundry research conducted by the Council since 1930 has now led to the formation of a Canadian

Research Institute of Launderers and Cleaners. Reports from the various laboratory divisions summarizing work in progress refer to investigations on chemical weed killers, including a review of the literature, and on the biochemistry of rust resistance. The Division of Chemistry has devoted a considerable amount of attention to problems relating to carbon black, leather, paints and rubber. It has developed a method for plucking poultry which has received many favourable notices. A special wax has been prepared which can be used for removing the pen-feathers, and by its use poulterers can prepare birds for market which are cleanly plucked and attractive. Much work has been done on the conservation of Alberta's natural resources, while in the Fire Hazard Testing Laboratory of the Division of Physics and Engineering, the testing and listing of domestic oil burners has been studied and the drafting of safety codes has received attention. A joint Associate Committee with the Dominion Department of Agriculture has investigated field crop diseases while another such committee is concerned with grain research including the frost injury of wheat, methods of determining moisture in grain and the effect of carbon tetrachloride on the quality of damp wheat in storage. Other associate committees are concerned with the storage and transport of food, weed problems, wool, parasitology and engineering standards.

Organon

THE first number of a new international review, *Organon*, has just been published in Warsaw by the Mianowski Institute. It is printed in French and English although all the authors are Polish, in order that a wide public may become familiar with the progress of scientific thought in Poland. The general character of the new publication can be gathered from the first group of contributions—"The Science of Science", "La Science, la religion et l'art", "The Man of Action and the Student", "Documents sur la psychologie de l'invention dans le domaine de la science", "Science and Scholarship in Poland to the Close of the Sixteenth Century", "Copernic", "Organisation de la science polonaise" and "Marja Sklodowska-Curie". The term 'science' is used in the widest possible sense, so that the new review will not be limited to contributions dealing only with the natural sciences. Two of the four historical articles have for their subjects the best known of Polish scientific workers, namely, Copernicus and Mme. Curie. It will be observed that the international character of science is well illustrated by the life and work of Mme. Curie. Polish by birth and French by marriage, her great discoveries were made with material from Bohemia which had been put at her disposal by Austrian authorities.

The Science of Science

THE first contribution to *Organon* attempts to analyse the 'science' of scientific investigations. We are reminded that the problems of science can be grouped according to different principles. Thus, they may be classified as being connected with the philosophy of science, with its psychology or with its sociology. Such groupings and others in which further subdivisions are made do not avoid overlapping but, according to Drs. M. and S. Ossowski, they do serve to indicate that there can be a 'science of Science'. Against this view it can be urged that these problems already have their positions in well-defined fields (psychology, sociology, the theoretical parts of the separate sciences, etc.) but the Polish authors argue that the scope of this 'science of Science' comprises investigations concerning very widely separated subjects and brings them into internal harmony. The problems are attacked by many different means, but even here new links can be forged to bring the whole of science into one harmonious whole. The growth of science requires an extremely wide and many-sided supplementary apparatus, and the building of this apparatus requires theoretical studies.

A Landmark of Horticulture

THE names of J. C. Loudon and his wife Jane Loudon will always be remembered gratefully by gardeners. Such exhaustive publications as the "Encyclopædia of Plants", the "Encyclopædia of Gardening", and the "Encyclopædia of Agriculture" led up to their culminating triumph, the "Arboretum et Fruticetum Britannicum". This was published in sixty-eight parts between January 1835 and July 1838, so that it is approximately one hundred years since this typographical monument was given to the public. Mr. W. Roberts, writing on "The Centenary of Loudon's 'Arboretum'" (*J. Roy. Hort. Soc.*, 61, Part 7, July 1936), gives some interesting information about the methods by which the extraordinary amount of knowledge upon trees and shrubs was brought together. About three thousand questionnaires were circulated, in the days before the penny post, and Loudon received a very gratifying number of replies, the originals of which have been consulted by Mr. Roberts. Many of them bear striking testimony to the popularity of the Loudons, for invitations to stay at country seats were very numerous. An application to the Duke of Wellington resulted in his lordship mistaking the word Beeches for Breeches, and the signature for C. J. London. This he interpreted as from the Bishop of London, and accordingly dispatched the famous Waterloo breeches to that puzzled gentleman. The "Arboretum" and the other publications contain a great deal of information which is still of the greatest use at the present time. It is inevitable that the march of knowledge should add considerably to these solid foundations, but one feels that the £10,000 which the Loudons paid in amassing the knowledge and publishing the text of the "Arboretum" are still bearing handsome interest for the horticultural fraternity.

Survey of India

THE General Report of the Survey of India for 1935 directs attention to the need for quicker revision of the maps of India. It was in 1905 that the Survey embarked on a scheme of 1 inch to 1 mile maps of

India, which was to be completed in twenty-five years and then revised every thirty years. Subsequent events led to a modification of the scheme. In 1913 it was realized that the allotted time was too short, and a smaller scale of map was sanctioned for the less populous areas. But the Great War and subsequent financial stringency still further curtailed the plan. By 1935 only two-thirds of the programme had been completed. Surveys are being carried out at the rate of about thirty-nine thousand square miles a year, and if this can be maintained the programme will be completed in about sixteen years. Meantime, the maps of a large part of India, except on a small scale, are much out of date and printed mostly in black only. The Report contains a key map showing the degree of obsolescence of various sheets. Maps of India, Burma and adjacent countries on the 'one million' scale are now practically complete and the sheets of the Carte Internationale are approaching completion. A separate publication of the Survey of India is an Index to Annual Reports, 1904–5 to 1926–27.

Discoveries in Antarctica

Some valuable details of new discoveries in Antarctica accompanied by photographs are contained in an article in the *National Geographic Magazine* for July by Mr. L. Ellsworth on "My Flight across Antarctica". It will be remembered that in December of last year, Mr. Ellsworth reached the Bay of Whales in the Ross Sea after a flight from Dundee Island, Graham Land. This took him over an entirely unknown part of Antarctica to the Pacific side of the Pole. South of Stefansson Strait he discovered a lofty rugged mountain range with an apparent trend between north-north-west and south-south-east. Farther on, other peaks appeared, one rising to 13,000 feet. Mr. Ellsworth made several landings in about lat. 80° S. and found a plateau at an elevation of more than 6,000 ft. He gave the names Hollick-Kenyon plateau to this elevated country, and James W. Ellsworth Land to the whole area between Hearst Land and Marie Byrd Land. The photographs of the new mountains do not suggest the block faulted mountains of Queen Maud Ranges, but rather the Andean ranges of Graham Land which, from Admiral Byrd's recent discoveries, would seem to continue into Edward Land.

Further light on this problem is shed by an article by Mr. W. L. G. Joerg in the *Geographical Review* of July on "The Topographical results of Ellsworth's Trans-antarctic Flight". Mr. Joerg has mapped the direction of the new ranges as far as available data allow, and his map appears to confirm the suggestion of R. Staub that the axes of the Antarctic Andes of Graham Land spread fanwise in Hearst Land. Each of the newly discovered ranges seems to be a continuation of one of the three-fold lines of Graham Land. The relation of these folds to the plateau land of Antarctica has still to be determined, and Mr. Joerg's suggested direction does not continue into Edward Land. Mr. Ellsworth's photographs also suggest that Stefansson Strait is narrower than previously supposed, or possibly that it is an embayment on the east of Graham Land and not a strait. Its eastern entrance lies mainly north of the seventieth parallel. The discoveries open a field for future ground exploration.

Recommended Values of Illumination

The Illuminating Engineering Society has issued a list of the values of illuminations which are recommended for various purposes. It has been prepared by the Technical Committee of the Society, and copies of the full recommendations can be obtained from the Honorary Secretary, I.E.S., 32 Victoria Street, S.W.1, price 6*d*. Since the candle-powers of electric lamps are known and the distance of the lamps from the work bench can easily be estimated, it is not difficult to estimate the candle-power. The committee recommends that if the task requires both discrimination and response, the foot-candle value should be at least 50. For severe and visual tasks such as fine engraving, sewing of dark goods, and discrimination of fine details of low contrast, the foot-candle value should not be less than 25. For prolonged critical visual tasks such as proof-reading, type-setting, drawing, reading, fine machine-work, fine assembling and use in large stores, a foot-candle value between 15 and 25 is recommended. A foot-candle value of 8–15 would be suitable for visual tasks such as detailed office work, skilled bench work and sewing on light goods and for retail shops. For less-exacting visual tasks, such as general office, large assembly work and classrooms, 5–10 suffices. For work of a simple character not involving close attention of fine details, 3–5 foot-candles is suitable. For casual observation where no specific work is performed, 2–4 foot-candles is regarded as sufficient.

Streamlined Trains

People who have travelled in the new lightweight high-speed trains may have wondered why this new development has not come into wider use, and look forward to the time when most passenger trains will be similarly streamlined. According to a report issued by Science Service of Washington, D.C., L. K. Sillcox, the engineer of the New York Brake Company, discusses this point in a report to the American Society of Mechanical Engineers. He says that only about 20,000 route miles of the main lines of the railroads of the United States are fitted by their curves, grades and traffic to be usable for lightweight trains that can go at 100 miles an hour. This length of railway is only about ten per cent of the total mileage of railroads in the United States. It is well known that crowds will gather to see a passenger locomotive go by if it is fitted with a metal shroud that helps its streamlining or presents what the public thinks is a streamlined appearance. But this shroud adds 13,000 lb. to the weight of the locomotive. Another drawback is that the equipment has to be built very robust. Like motor-cars, the internal equipment has to be turned over and renewed every few years. In addition, any new railroad rolling stock has to be designed so that it is in keeping with the older equipment. A large reserve of the old equipment has to be maintained to meet the changing traffic demands made on it. Some engineers are afraid that there may be a public reaction after the very pleasant boon which the railways afforded when streamlined trains were first used. There is evidence of dissatisfaction when the public learns that a 100–120 miles an hour train is placed in revenue service on a 50–60 miles an hour schedule. Even although the maximum speed has been attained *en route*, the public feels that it has been misled.

Agricultural Research Institutes in Great Britain

THE Ministry of Agriculture has now published the report of the work of the agricultural research institutes in the United Kingdom for 1933–34 (London: H.M. Stationery Office; 5*s*. net). Besides describing the investigations carried out at the forty-four principal institutes, the report deals with the work at various advisory centres and special State-aided researches carried out in different parts of the country. The problems concerned cover a wide field, including soils, plant nutrition, physiology, breeding and disease, dairying, animal nutrition, breeding, diseases and pests, food preservation and transport, and agricultural engineering. Should anyone desire further information, a list of papers published from each centre is supplied so that reference to the original source of the work is available, and inquiries may also be addressed to the director of the institute or person concerned, the names and addresses of whom are listed.

The American Amaryllis Year Book

THE American Amaryllis Society has issued vol. 2, its Year Book for 1935 (from the Editor, Dr. Hamilton P. Traub, Mira Flores, Orlando, Florida, U.S.A.). It is dedicated to Theodore L. Mead, in recognition of his pioneer work with hybrid *Hippeastrum* plants. Gardeners are familiar with narcissi, they bestow a rather occasional interest upon day lilies (*Hemerocallis* spp.), they cultivate *Alstrœmeria*; but most horticulturalists have not yet realized the wonderful beauty displayed by the new hybrids of *Hippeastrum*. The Society has an international outlook, for a large part of the volume is devoted to regional activities in Australia, Kenya, Europe, and all parts of America. A section on "Description and Phylogeny" quotes *inter alia* from Dr. J. Hutchinson's recently published volume on the classification of monocotyledons. Robert F. Ruthruff contributes a paper describing the alkaloids found in various Amaryllidaceæ, and the late Dr. David Griffiths directs attention to "Opportunities for Breeding with Daffodils". Two valuable papers by Miss Ida Luyten and Dr. Traub introduce new methods of vegetative propagation of amaryllids. Fifteen papers deal with culture, five with curing, storage and forcing, and a similar number with marketing. The editor has introduced the idea of quoting one or two abstracts from scientific papers relevant to *Amaryllis* culture, and though the index shows nearly sixty papers, no subject appears to have inadequate treatment. Plans have already been made for publishing year books so far ahead as 1938; the Society occupies a position of great utility and high æsthetic value.

Early Photographs

THE June issue of the *Alumnus Chronicle* of the University of St. Andrews contains an article by Mr. J. H. Read describing a collection of prints by early photographers which illustrate the local development of the art and have been presented to the University by Mr. James Thomson of Inverness. The oldest photographs of the collection are of buildings in St. Andrews produced by the Calotype process about the year 1840. Portraits of St. Andrews worthies, for example, Sir Lyon Playfair and Sir David Brewster, by the process date from about 1850. The majority of the photographs are albumen prints from wet collodium plates taken during the next twenty years, and include portraits, scenery and reproductions of pictures. The article is illustrated by reproductions from paper negatives by Thomas Rodger of a St. Andrews fishing quarter in 1843, and a portrait of Prof. George Day, professor of medicine, 1850, both of which are remarkably good.

Films and their Utilization

THE current number of *Film Progress* is in two parts. It contains the usual supplementary bulletin to the National Encyclopædia of Films. In this section are noted a good number of films, both 35 mm. and 16 mm., of G. B. Equipments and Pathé. Silent films of Ensign and C.I.B.E.F. are also listed. The other section deals mainly with the educational value of the sound film. This is in effect a résumé of the arguments put forward by C. F. Hoban in a symposium on "Sound and Silent Films" held at the University of Chicago. The arguments are well stated, but the article reads too much like special pleading, seeing that the arguments for the silent film presented to the symposium are not mentioned. We hope that they will be stated in a future number.

Third World Power Conference

THE following official delegates have been appointed to represent the Government of the United Kingdom at the Third World Power Conference and Second Congress, International Commission on Large Dams of the World Power Conference, to be held concurrently in Washington, D.C., on September 7–12: Viscount Falmouth, Mr. N. G. Gedye, Mr. T. Hardie, Mr. J. M. Kennedy, Dr. F. M. Lea, Mr. Charles H. Merz, Sir Archibald Page, Mr. C. Rodgers, Dr. F. S. Sinnatt and Mr. E. T. Williams. The final time-table for the Conference has now been announced. The joint opening session will be held in Constitution Hall, Washington, on Monday, September 7, at 8.30 p.m. Business sessions will be held earlier on the same day and throughout the week. There will be an address by the President of the United States on September 11 at 2 p.m. followed by a garden party and reception at the White House.

Building Exhibition at Olympia, London

THREE HUNDRED AND FIFTY firms and associations have already booked space in the twentieth biennial Building Exhibition which is to be held at Olympia, London, on September 16–30. This number of exhibitors is in excess of the number which exhibited on the last occasion in 1934, and an increase of about 10 per cent in the total number may be expected. The Department of Scientific and Industrial Research is again to have a large exhibit, and this will cover not only the work of the Building Research Station, but also that of the Forest Products Research Laboratory, Princes Risborough, and the National Physical Laboratory, Teddington. The Building Research Station exhibit will deal with plastering materials; common types of failure caused by using unsuitable material or by faulty construction; concretes, with special emphasis on light-weight concrete; further work on the driving of concrete piles; the measurement of strain on masonry structures; and the weathering of building stone. The work of the Forest Products Research Laboratory illustrated in the Exhibition will deal with the correct moisture content of timbers for various purposes; wood-working, with special reference to new and difficult timbers; and wood preservation and protection against the death-watch and other beetles. The National Physical Laboratory's exhibit will deal chiefly with building acoustical problems, models being shown of typical quiet and noisy rooms. Short-length films are to be shown by the Department on its stands.

Observations on Comets

A CONSIDERABLE number of observations of Peltier's comet are now available, and the Rev. Dr. M. Davidson has computed a new orbit, using observations from May 16 to July 15, the latter being made by Dr. W. H. Steavenson and independently by Mr. Will Hay. The period appears to be about 1500 years, but observations from the southern hemisphere, in which the comet can be followed up to October, will enable computers to obtain a more accurate period. The comet is rapidly moving south, and will not be visible in these latitudes after August 6. A comet of sixth magnitude was discovered by Kaho on July 17, and a number of observations have since been made at various observatories and also by members of the British Astronomical Association. The orbit given below was computed by Whipple and Cunningham, but as the observations used were very rough, the orbit is only approximate. Dr. Crommelin, having received more accurate observations, is now engaged in computing a general orbit. The comet is receding from the earth and sun and is fading rapidly.

Orbit of Comet 1936a (Peltier)
Computed by Rev. Dr M Davidson

T	1936 July 8 95141 U.T.

Announcements

ROBERT ESNAULT-PELTERIE has been elected a member of the Division of the Applications of Science to Industry of the Paris Academy of Sciences in succession to the late Jean Rey.

AT the quarterly meeting of the Royal College of Physicians held on July 30, the Weber-Parkes Medal and Prize were awarded to Sir St. Clair Thomson for his work on tuberculosis of the larynx, and the Moxon Gold Medal to Prof. Edward Mellanby for his work on the problems of nutrition. The Harveian Oration will be delivered by Sir Walter Langdon-Brown on October 19, at 4 p.m. Dr. Arthur Hurst has been appointed Harveian Orator for 1937 and Dr. E. A. Cockayne Bradshaw Lecturer for 1937.

THE Royal Academy of Belgium has made the following awards: Lefebvre Prize to MM. Wattiez and Sternon; Laurent Prize to M. R. Bouillenne; Van Beneden Prize to M. J. Brachet and grants from the De Potter Fund to M. A. Gardedieu, M. Capron, M. van den Bruel and M. Florkin.

DR. GOTTLIEB HABERLANDT, emeritus professor of botany in the University of Berlin, has been made an honorary member of the Academy of Sciences of Vienna.

THE Austrian Society for Roentgenology will hold its annual meeting at Vienna on September 4–8. Further information can be obtained from Allgemeines Krankenhaus, Zentral-Roentgen Institut, Alserstrasse 4, Wien 1.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

Junior assistants (physics or chemistry) in the Chemical Defence Research Department (War Department)—The Chief Superintendent, Chemical Defence Research Department, 14 Grosvenor Gardens, S.W.1 (August 12).

A lecturer in electrical engineering in Walsall Technical College—The Director of Education, Education Offices, Council House, Walsall (August 15).

An assistant lecturer and demonstrator in civil engineering in University College, Cardiff—The Registrar (August 19).

A part-time assistant lecturer in the Department of Physics and Applied Physics in the Technical College, Cardiff—The Director of Education, City Hall, Cardiff (August 24).

An assistant director of the Plant Pathological Laboratory, Harpenden—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1 (August 31).

A senior assistant in the Department of Surgery of the Royal Veterinary College—The Secretary (August 31).

An assistant curator in the Royal Albert Memorial Museum, Exeter—The Town Clerk, Exeter (August 31).

A lecturer in physiology in the University of Western Ontario, London, Ontario, Canada—The Dean of the Medical School.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 250.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Energy of Formation of 'Cyclol' Molecules

ACCORDING to the cyclol theory of the structure of proteins[1]—a *working hypothesis* recently put forward in these columns—the polypeptide, the essential unit in the molecule on the classical theory, is replaced by the cyclized polypeptide (Fig. 1): correspondingly the classical peptide links (joining one pair of C,N atoms) are replaced either by the double peptide links (joining two pairs of C,N atoms) or by the triple peptide link (joining three pairs of C,N atoms) (Fig. 2). The reaction

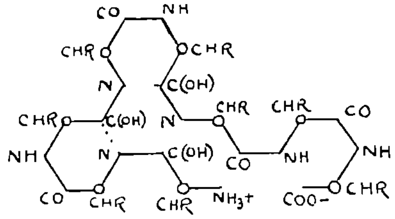

FIG. 1.

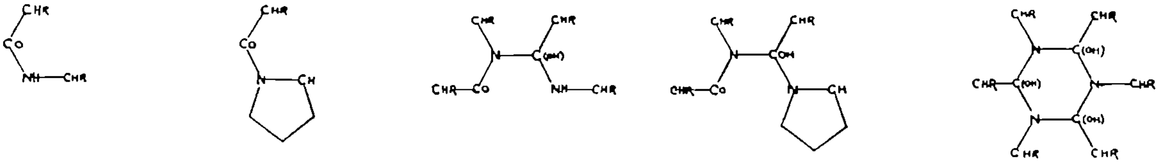

Single peptide links. Double peptide links. Triple peptide link.

FIG. 2.

polypeptides $\rightleftharpoons$ proteins

is thus regarded as a ring chain tautomerism[2], which takes the form

$$\geqslant\mathrm{N}\quad(\mathrm{HO})\,\mathrm{C}\leqslant\ \rightleftharpoons\ >\mathrm{N}-(\mathrm{HO})\,\mathrm{C}< \qquad (1)$$

if the appropriate groups are in the imide form, and the form

$$>\mathrm{NH}\quad\mathrm{O}=\mathrm{C}<\ \rightleftharpoons\ >\mathrm{N}-(\mathrm{HO})\,\mathrm{C}< \qquad (2)$$

if they are in the amide form.

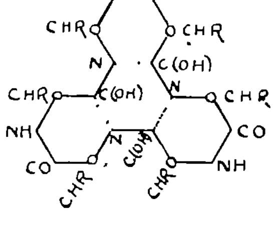

FIG. 3.

The precise data required for an estimate of the energy balance in the process of formation of cyclol molecules from polypeptides are not yet available, but we may consider cyclol 6 (Fig. 3) as an indication of the situation, in the hope of directing attention to the fact that certain data are urgently required.

The figures[3] for heats of formation of various links, in kilogram calories, are as follows:

C—O	82·8	(alcoholic ethers)	C=N	119·6	('estimated')
C=O	177·8	(ketones)	O—H	109 5	(H_2O)
C—N	61·5	(amines)	N—H	83·3	(NH_3)

With these figures, the energy changes are as follows:

One amide to imide transformation,

$$(177{\cdot}8+61{\cdot}5+83{\cdot}3)-(82{\cdot}8+109{\cdot}5+119{\cdot}6)=+10{\cdot}7.$$

One transformation of type (1),

$$(119{\cdot}6)-2(61{\cdot}5)=-3{\cdot}4.$$

One transformation of type (2),

$$(177{\cdot}8+83{\cdot}3)-(82{\cdot}8+109{\cdot}5+61{\cdot}5)=+7{\cdot}3.$$

According to these figures, the formation of cyclol 6 from a closed polypeptide consisting of 6 residues requires 21·9 kilogram calories if the polypeptides are in amide form throughout; if the three links concerned are already in the imide form, energy amounting to 10·2 kilogram calories is emitted. In these calculations, no allowance is made for resonance, which amounts to 20 kilogram calories for acetamide.

The calculation for the process of linkage (1) suggests that if the synthesis of proteins is a process of cyclization of polypeptides (or indeed if it is a process of polymerization of substituted diketopiperazine molecules), it is facilitated if the appropriate groups are in the imide form. The implication is that certain enzymes operate directly on the substrate by imposing on some of its (CO,NH) groups, the imide form $-C(OH)=N-$. This deduction from the cyclol hypothesis gains support from the researches of Bergmann and his co-workers on dipeptidase, which led them to assume[4] that the "hydrogen atom becomes rearranged under the influence of the enzyme in such a way that the amide form of the dipeptide is changed to the imide form $-CO-NH- \rightarrow -C(OH)=N-$".

The implications of the calculation for the process of linkage (2) are explored in the accompanying letter by my colleague, F. C. Frank.

[2] See, for example, J. W. Baker, "Tautomerism" (1934), p. 38.

[3] The figures of Pauling and Sherman given in *J. Chem. Phys.*, 1, 606 (1933), calculated on the basis of the value of 208 kilogram calories for the heat of dissociation of N_2, have been modified to take account of the revised value of 169 kilogram calories (see Mulliken, *Phys. Rev.*, **46**. 144 (1934); Herzberg and Sponer, *Z. phys Chem.*, B, **26**, 1, though this modification is without effect on these calculations.

[4] *J. Biol. Chem*, **109**, 325, 329 (1935).

WRINCH[1] recently proposed that in monolayers or globular molecules of proteins, polypeptide chains are knitted into a fabric by the bonding process

$$>C=O + HN< \rightleftharpoons >C(OH)-N<,$$

which Frank[2] had shown to be required in keratin to make permissible the structure Astbury deduced for it by X-ray crystallography. It is desirable to estimate the energy balance of this process, which is chemically analogous to lactam-lactim tautomerism, or to the ring closure in sugars associated with mutarotation.

Taking link values of heat of rupture from Pauling and Sherman[3], we find the process of linkage represented above is endothermic by about 7·3 kcal., while a lactam-lactim transformation is 10·7 kcal. endothermic, without allowance for resonance energies in either case. Resonance in the lactam form increases both these figures by some 20 kcal., if taken as the same as in acetamide: there must be a similar but presumably smaller resonance energy in the lactim, but the 'cyclol' molecule in itself offers no chance of constructing a resonant system.

Though these are not free energies, and in any event not very accurate, they appear certainly too large to allow the equilibrium to rest close to the right hand of the equation, as the theory requires, so that we must either abandon the theory or find some compensating source of energy. This is provided in the keratins by strain in the side-chain cross-linkages, which Astbury[2] and Speakman[4] have shown to provide the main driving force of contraction from the β-form. In the proposed 'cyclol' monolayers, we have a similar source of energy which we may call a heat of crystallization, for the cyclization into a compact strainless form is evidently at the same time a process of two-dimensional crystallization; but this by itself cannot be sufficient.

An additional source is provided by hydration (or association through hydroxyl bonds generally), which is well known to stabilize lactims, non-chelate enols, and hydroxylic tautomeric forms in general[5], a fact directly related to their superior solubility in water and other hydroxylic solvents. Not only the hydroxyls but also the nitrogens, which are more aliphatic in nature in the cyclized form, are available for hydration: protein hydroxyls can also associate with each other. Each hydroxyl bond formed may be supposed to provide energy of the order of half the internal latent heat of vaporization of ice, thus about 5 kcal., so that the whole may be a sufficient compensating source of energy, about 20 kcal.

Thus it appears that if the protein molecules are fabricated with the aid of this linkage, they can only be stable when hydrated. Any conditions tending to dehydration will render the protein excessively liable to opening into chain forms, unless restrained by side chains or deprived of catalysts necessary for transformation. Mildly dehydrating conditions should be most effective because water is a catalyst for transformation as well as a stabilizer of one form. So long as the rings only occasionally open they can re-form in the same configuration, but as soon as the opening becomes too frequent this will cease to be the case and they will then re-form in altered structures, derived more directly from open chains. This conforms with all observations on the processes of degeneration and denaturation, including Astbury's X-ray studies of these processes[6,7]. Thus what seems at first to be a destructive obstacle to the theory may be capable not only of reconciliation with it, but even of enhancing its effectiveness.

Insect Coloration

IN the article on the Oxford Congress of the South Eastern Union of Scientific Societies in NATURE of July 11, p. 88, reference is made to the address of the president, of which the main topic was the coloration of insects by natural selection. Prof. Hale Carpenter is reported as saying:

"Sometimes it pays an insect to change its appearance according to whether it appears in a dry or in a wet season. Poulton pointed out that a dry season is one of scarcity of food, and certain butterflies then remain inconspicuous and of skulking habits, whereas in a wet season they are conspicuously coloured, and they can afford to allow some of the species to be eaten by reason of their number."

Prof. Hale Carpenter referred to an African *Charaxes*, which is conspicuous in the wet season but in the dry assumes a dead-leaf-brown and deliberately hides itself among clusters of dead leaves. To assert that an insect *deliberately* hides, is going far. When bug hunting in Australia and Sumatra, it seemed to me that the butterflies all made for shade behind leaves, when not madly careering in the sun. May not the food in the two seasons vary, not merely in quantity but in quality? It certainly will. The temperature also. As we know nothing about the relation of coloration to quality of food, the subject is beyond discussion, at present. Darwinian discussion is largely on 'Alice' lines. No chemist can believe in change by any process of direct mimicry—nor even a MacBride. Nature is held under strict enzymic control, though inspection of any good collection shows the actual variations are very wide. Discussions too are often wide of the mark: if they were all scientific, our shelves would have an easy burden. Are the morals of the insect world on so high a plane that it can be asserted that there has never been a cross of mimetics? Mistakes, we know, are made even in the best regulated families.

HENRY E. ARMSTRONG.

55 Granville Park,
Lewisham, S.E.13.

PROF. ARMSTRONG's criticisms are easily met. It is *not* going too far to "assert that an insect *deliberately* hides". The taking temporary shelter from sun is a different matter from assuming a position of complete rest in surroundings best suited to concealment for long periods. The case I mentioned was undoubtedly deliberate choice of a cluster of dead leaves, among others, by a *Charaxes*. I have repeatedly watched the Pierine butterfly *Eronia cleodora*, having been disturbed from undergrowth where it had settled late in the evening, deliberately settle again, after previously fluttering around, among the half-dead leaves from which it had been disturbed and with which its patchy yellow underside closely matched. The late Dr. G. B. Longstaff recounts the same experience on p. 194 of his book, "Butterfly Hunting in Many Lands", and gives a very accurate coloured plate to illustrate the point.

Has Prof. Armstrong never studied photographs of procryptic geometrid moths on the bark of trees, which do not rest in haphazard positions but take up an attitude bringing the edges of their front wings into line with the edge of a crack in the bark, and putting the main features of their pattern into harmony with the surface on which they rest ?

Prof. Armstrong says that "No chemist can believe in change by any process of direct mimicry". It is a little difficult to understand precisely what is meant. Is he aware of the facts concerning *Papilio dardanus* ? In this butterfly the light yellow pigment of the male, and the ancestral form of female like it, fluoresces in ultra-violet light, but in the mimetic forms of female the fluorescence has been lost : this surely implies a chemical change.

The last point raised by Prof. Armstrong is a form of the old and out-of-date argument that mimicry is merely an expression of affinity.

No one, I think, would venture to assert that the close mimetic likeness of a moth to a Hymenopterous insect such as an ichneumon-fly is due to hybridization ! Would Prof. Armstrong account for the likeness of a moth or a beetle to a bird-dropping in the same way ? Such a resemblance is of the same class as mimicry, and an explanation other than natural selection which accounts for both has yet to be found.

Palæozoic Seismicity

EVIDENCE of contemporaneous disturbances during the deposition of Ordovician strata has recently been collected at localities in the Irish Free State including Portraine, Balbriggan, Raheen Bridge and Tramore. This comprises breaking up and slumping of limestone beds, rapid alternations of shale and graded sand (greywacke sedimentation), breccia beds between sub-parallel undisturbed layers, and anti-dune wave-crests in mud. The cause probably lies in seismicity associated with the instability of the Lower Palæozoic geosyncline.

It now seems possible to demonstrate that the 'crush-conglomerates' and 'thrust-conglomerate' distinguished by Reynolds and Gardiner[1] at Portraine are paene-contemporaneous effects, since the Portraine limestone contains unbroken layers intercalated between beds brecciated *in situ*, and 'landslip' masses (Fig. 1). North-west of Balbriggan, one has a repetition of several of the features which Henderson[2] at Girvan ascribed to seaquakes and tidal waves. In County Waterford, greywacke beds with breccias have been examined on the coast north of Raheen Bridge. The shaly fragments in these remain so sharply angular that they must have become embedded in their present sandy matrix almost as soon as they were disrupted. The possibility of tsunamis, after earthquakes, carrying shore sand out to sea among disturbed shaly sediments, as suggested by Bailey and Weir[3], must be carefully considered. In the Carrigaghalia Series of Reed[4], on the north side of Doneraile Cove, Tramore, wave-crests of mud, in the anti-dune phase, have been discovered preserved in tuffaceous sand. The only explanation in this case seems to be that the sandy detritus was deposited by a tsunami, the swift passage of which induced the anti-dunes. Examination of one wave-crest about ¾ inch high, indicates that it is in no way a compressional structure due to pressure by an overlying column of sand differentially weighted, but shows loosening out of the muddy laminæ.

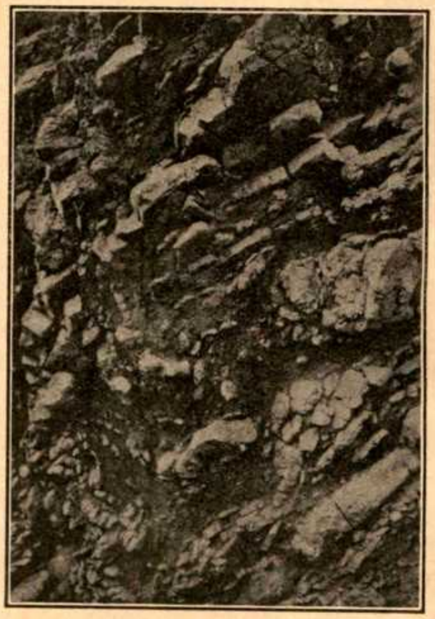

FIG. 1. Slumping of limestone beds in shale. Height of section, about 8 feet. Priest's Chamber, Portraine, Co. Dublin.

This work casts grave doubt on the views of Kilroe and McHenry[5] regarding 'intrusive tuffs' in south-eastern Ireland. These anomalous clastic beds probably originated as water-laden sand which, under seismic conditions, might behave with the mobility of an igneous rock.

The Irish disturbances I have noted are of Caradocian age—the Portraine beds may be correlated with the Robeston Wathen limestone in Wales —and this epoch may be regarded as one of marked seismicity.

There is no doubt that seismic activity must have prevailed at many stages during the development of the Lower Palæozoic geosyncline. Certain breccias in Arenig greywackes of the west of Ireland are unquestionably attributable to it. One example figured by Gardiner and Reynolds[6] from Glensaul may be taken as typical. It occurs sharply bounded between undisturbed layers, the narrowness and unbroken nature of which exclude the contingency of frictional brecciation. A similar interpretation seems to apply to the 'crush-conglomerates' described by Lamplugh[7] from the Manx Slate Series. In the Lower Cambrian (?) of Howth, near Dublin, greywackes and shaly breccia—'sherd-schist'—appear to me to provide at a still earlier period an indication of contemporaneous disturbances.

As an example from another geosyncline, there are the graded sediments of the Middle Devonian of New South Wales. From these, Benson[8] figures an example in which a claystone layer has two anti-dune wave-crests picked out in tuffaceous sand. He describes the latter as 'intrusive'. But it is more likely to have been carried into place by a tunami. The specimen, I believe, has been figured upside down.

It may be added that a recurrence of seismic conditions in carboniferous times in the Dublin district seems to be indicated by anti-dune wave-crests in mud which have been found in beds of Yoredale age at Loughshinny. These beds show rapid alternations of shale and graded sand. Their evidence is corroborated by brecciation *pari passu* with deposition in D_2 limestone at Curkeen Hill quarry.

Density and Compressibility of Solid Hydrogen and Deuterium at 4·2° K.

IT has been shown by Bennewitz and Simon[1] that the influence of zero-point energy on the properties of a condensed substance is very great for substances of low boiling point. The effect is most marked in helium[2], where it actually plays the chief part in determining the properties; but it is large, too, in hydrogen, a substance which is particularly interesting as it possesses two isotopes which have identical binding forces but very different zero-point energies.

Certain of the properties of the solid phases have been measured already, by Simon and Lange for hydrogen[3] and by Clusius and Bartholomé for deuterium[4], among them being the specific heats at constant pressure, the heats of evaporation and melting, and the molar volumes at the triple points. Clusius and Bartholomé have discussed in their very interesting paper the influence of zero-point energy by comparing the properties of the two isotopes. Nothing was hitherto known, however, of the compressibilities. These are of special interest because the zero-point energy gives rise to a pressure $p^{(\circ)}$, and its variation with volume to a compressibility[2] $K^{(\circ)}$, which, as a preliminary estimate shows, will be an important part of the total compressibility. At the same time, a knowledge of the molar volumes at the boiling point of helium will give us very nearly their values at absolute zero, and, using the known values at the triple points, the mean thermal expansions.

For obvious reasons, we had to use a pyknometer method. The only substance available as a filling liquid is liquid helium, and since its compressibility is very much greater than that of solid hydrogen, the method cannot be one of high accuracy. But as hitherto even the order of magnitude was not known, we thought it worth while to carry out the experiment.

A vessel of known volume (about 4 c.c.) was attached to a helium liquefier of the expansion type; it was nearly filled with condensed hydrogen (or deuterium), and when this was solid, completely filled with liquid helium at a pressure of about 100 kgm./cm.^{2}. By letting out successive amounts of helium and measuring them as a gas at room temperature, and afterwards measuring in the same way the hydrogen, the density of the solid hydrogen at each pressure could be calculated. The results are given in the accompanying table.

	Hydrogen	Deuterium
Density (gm./cm.^{3}) at 1 kgm./cm.^{2} and 4·2°	0·0890 ± 0·0004	0·2059 ± 0·0010
Molar volume (cm.^{3}) at 4·2°	22·65 ± 0·1	19·56 ± 0·1
Compressibility (cm.^{2}/kgm.) at 4·2° (average from 1 to 100 kgm./cm.^{2})	(5·0 ± 0·5) × 10^{-4}	(3·3 ± 0·7) × 10^{-4}

As to the compressibilities, it may be remarked that the curve of volume against pressure is, as expected, not a straight line. In the above table, however, only the mean compressibility between 1 and 100 kgm./cm.^{2} is given, since it is known more accurately than the compressibility at any given pressure. But it may be noted that the compressibility at 100 kgm./cm.^{2} is for both isotopes roughly half that at 1 kgm./cm.^{2}. For the thermal expansion, assuming for a rough estimate that it is proportional to C_p, and combining the molar volumes at 4·2° with those at the triple points, we find that at a given temperature the expansion coefficient of deuterium is about half that of hydrogen.

We intend to publish a more detailed account of these experiments, and will postpone until then the theoretical discussion of our results, which we hope to consider also from the point of view of F. London's treatment of helium[2]. Here we should like to point out only that, for hydrogen, $p^{(\circ)}$ amounts to about 1,000–2,000 atm., and $K^{(\circ)}$ accounts for a very great part of the total compressibility.

Our sincere thanks are due to Dr. N. Kürti for his constant help in carrying out the experiments.

Quantum Relationship of the Light-emitting Process of Luminous Bacteria*

WE have studied the relation between the oxygen consumption and the light intensity of a suspension of luminous bacteria (*Photobacterium phosphoreum*) by measuring simultaneously, at different concentrations of potassium cyanide, the oxygen consumption by the ordinary Warburg method and the light intensity with the aid of a photometric method.

It could be shown that the oxygen consumption consisted of two main parts: one of which was inhibited completely by about 0·001 mol. potassium cyanide, whereas the other decreased slowly with increasing concentration of the cyanide and in proportion to the light intensity.

In plotting the light intensity against oxygen consumption, the lower part of this curve was a straight line, giving the percentage of oxygen consumed in the light-emitting process. This proved to be 19 per cent of the total amount of oxygen consumed.

As the light emission could be measured in absolute units, the number of molecules of oxygen consumed per quantum of light emitted could be computed. At 16° C. the mean value obtained was 500 molecules of oxygen per quantum.

It seems remarkable that, whereas the percentage of oxygen consumed in the light-emitting process proved to be constant under different conditions and at different temperatures, the light intensity varies a great deal. It must be concluded, therefore, that the efficiency of the light-emitting process is dependent on various, as yet unknown, factors.

The Lower Regions of the Ionosphere

IN our recent letter to NATURE[1], we did not mean to infer that reflections from the 60 km. level had not been found before. So early as 1930, Appleton[2] noticed reflections of this type. In 1935, Mitra and Syam[3] recorded reflections from this level using the pulse method of Breit and Tuve. The only addition we made to existing knowledge was that this high level forms the top of a region extending from 40 km. to 55 km. and that there is a lower region from 5 km. to 30 km. high. Practically the same discovery was made in England by Watson Watt and his co-workers[4]. In accordance with Mitra's suggestion[5], we propose to call these the *D* and *C* regions.

The following observations may be of interest. The height of the lower boundary of the *C* region is less in summer than in winter; it rises slightly during the night. The *C* region is so strongly reflecting in the summer months that it weakens the reflection from the *D* layer. Hence the *D* layer is usually found in the winter season. When thunderstorms or strong winds are present, the *C* region is very turbulent.

On April 22, 1936, a violent magnetic disturbance was recorded at Cheltenham, Md. On the same day, we observed that the *C* region was fluctuating violently (Fig. 1) and its lower edge approached very close to the earth's surface (1–5 km.). At that time no signals were received upon the 20-metre transmission band from any distant stations.

When the U.S. stratosphere balloon *Explorer II* passed through the 60,000 ft. level, its signals became weak[6]. Our explanation of this phenomenon is that the balloon was actually above the top of the *C* region; hence the signals, which had been reflected back to the earth when the balloon was in the *C* region, were later reflected out into space.

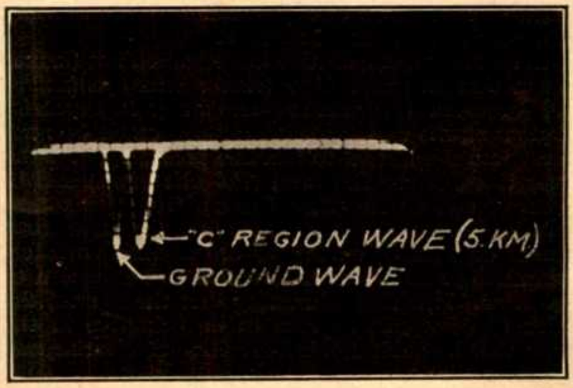

FIG. 1. Ground pulse and its reflection from the *C* region. On this scale, the *E* layer would appear about three inches and the *F* layer about six inches to the right.

Stereoisomeric Nature of Oxidation and Fermentation

I HAVE investigated with the aid of the Warburg technique the action of optically isomeric nicotines upon alcoholic (*Torula utilis*, *Saccharomyces exiguus*) and lactic (*Bacterium Delbrücki*) fermentations of glucose dissolved in the external solution; upon oxidation of exogeneous glucose by *T. utilis*, *S. exiguus*, *Oidium lactis*, *Bacillus subtilis*, *B. mycoides*, *Sarcina lutea* and *Bacterium Schützenbachi*; upon oxidation of lactate by *O. lactis* and of ethyl alcohol by *B. Schützenbachi*; and upon respiration of stored glycogen in *T. utilis*, *S. exiguus* and *B. subtilis*. It was found that in these microbes all fermentations are more strongly depressed by *l*-nicotine than by *d*-nicotine, but all oxidations are, conversely, more strongly depressed by *d*-form.

I have also investigated the action of optically isomeric nicotines upon the metabolism of slices of mouse tissue. The respiration of the stored glycogen in the liver of the mouse proceeds in two linked phases, the first of which (anaerobic) is more sensitive to nicotine poisoning and accounts for the fact that *l*-nicotine inhibits the whole respiration more strongly than *d*-nicotine. The oxidation of exogeneous glucose and of lactate in the slices of starved liver are direct, and therefore more sensitive to *d*-nicotine. Glycolysis of the grey substance of the brain in mice is *l*-sensitive to nicotine and of the same order of magnitude as the endogeneous respiration in the liver, and it is therefore probable that lactic acid production is the limiting anaerobic link in the latter case.

An extensive comparative investigation has further shown that in green Algæ (*Rhitoclonium fontanum*) and Protozoa (*Palamecium candatum*, *P. Cursaria*, *Euglena viridis* and *Eudorina elegans*) oxidations are direct and *d*-sensitive to nicotine poisoning. At the same time, in the flatworm (*Polyulis nigra*) and in livers of adult pike (*Esox lucius*), frog (*Rana temporaria*), green linnet (*Chloris chloris*), and fowl (*Gallus domesticus*) oxidations are coupled with fermentations, and are more sensitive to the action of *l*-nicotine. It is also interesting that the liver of the chick (3 days old) appears to be primitive in the sense that its oxidation is *d*-sensitive to nicotine and therefore direct.

The precision of the results obtained in the analysis of oxidation and fermentation with the aid of optically isomeric nicotines may perhaps be due to the fact that both the pyridine and pyrrol groups of nicotine enter into the composition of enzymes catalysing carbohydrate breakdown[1] which are therefore in some way specifically destroyed by the nicotine.

A complete account of these investigations will be published shortly.

Interaction of Heavy Nuclear Particles

SOME time ago, it was suggested that the interaction between neutrons and protons goes on via particles of small mass—electrons (positrons) and neutrinos—somewhat in the same way as electromagnetic interaction (compare Coulomb's law) is transferred by photons[1]. After a recent discussion of the problem by Heisenberg[2], who pointed out the necessity for changing the r^{-5} law to one involving r^{-7} or r^{-9}, it seems desirable to perform the calculations for the magnitude of interaction in the most simple manner.

Indeed, the most essential point proves to be the fact of energy transfer *by a pair of particles*, and not by a single photon as in the usual electromagnetic case. For the magnitude of the interaction at the small distances which are of interest, even the statistics of the transferring particles is not important, or even the kind of partners implied (electron and neutrino, or two neutrinos). We have worked with simple scalar equations of wave type, or of the type of Schrödinger's second order relativistic equation. Starting with Fermi's assumption for the interaction between heavy particle and neutrino-electron field ($g\,\varphi_1\varphi_2$), or with a more general expression $\left(g\,\frac{\partial^n\varphi_1}{\partial t^n}\,\frac{\partial^m\varphi_2}{\partial t^m}\right)$ and applying the elegant method of Dirac's quantum electrodynamics, we get for the magnitude of interaction expressions proportional to $\frac{g^2}{r^5}\,I_1(r)$, or $\frac{g^2}{r^{2m+2n+5}}\,I_2(r)$. The integrals $I(r)$ are equal to 1 for $r \ll h/mc$ and vanish at great distances. Thus we get the remarkable result that the interaction depends chiefly on the presence of two particles, just as does the probability for β-decay[3]. If needed, one can introduce the relativistic equations for heavy particles and work with an interaction formula which is very similar to Breit's, but not identical with it.

So far as the order of magnitude is concerned, we can compare the interaction at the distance r_0, equal to the radius of a heavy particle, with the self-energy μc^2. For $r_0 \sim 10^{-13}$, which is assumed to be the most reasonable, the best choice is the energy expression, proportional to $\frac{g^2}{r^{11}}$ or $\frac{g^2}{r^{13}}$, which results from that form of the interaction between heavy and light particles and is that found to be the best for the purposes of β-decay theory[3].

We may note that until now no classical analogy for the field of two particles has been found, so that the above considerations rest on essentially non-trivial results of quantum electrodynamics.

Dependence of the Herschel Effect upon the Surrounding Gas Medium

THE Herschel effect—the weakening of the latent photographic image by means of light—is observed, as a rule, in the red and infra-red region of the spectrum. Recent investigations, however, show that under certain conditions the Herschel effect is observed in regions of the spectrum, where usually a normal photographic effect prevails. If, then, the Herschel effect is stimulated by the parallel reaction which accompanies the main photographic process, it is reasonable to suggest that the surrounding gas medium is involved in the reaction.

It was suggested to me by Prof. Narbut that an investigation of the influence of the gases oxygen, nitrogen, hydrogen and carbon dioxide and also of a vacuum upon the Herschel effect would repay investigation. Diapositive plates of the "Photo-Khim-Trust" works of Moscow and Kiev were used. The Herschel effect was obtained by red light (a photographic lamp of 25 candle-power).

Investigations were carried out with seven series of plates, with the following results:

(1) In oxygen, the Herschel effect is much more intensive.

(2) In nitrogen and carbon dioxide, the Herschel effect has almost disappeared.

(3) In hydrogen, the red light gives but a normal photographic effect—additional darkening of the plate. Hence the medium is apparently essential in

the mechanism both of the normal photographic effect, and also the Herschel effect.

Further work with other photographic materials is in progress.

Ozone as a Heating Factor in the Atmosphere

THE vertical distribution of temperature in the upper layers of the atmosphere as affected by ozone has been carefully calculated. Taking the vertical distribution of ozone as found by Gotz, Meetham and Dobson, and using new absorption coefficients, it was possible to derive the energy absorbed in the course of one day. Four days were selected to show the yearly change.

The solar radiation below 3000 A. was assumed to be a black-body radiation of 5,910° K.; for all the other wave-lengths, the values given by Abbot were used.

Secondly, the nocturnal radiation has been studied. For each layer the absorption of radiation from the earth and from all the other layers, and the re-radiation of this layer have been calculated. The atmosphere was divided into six layers.

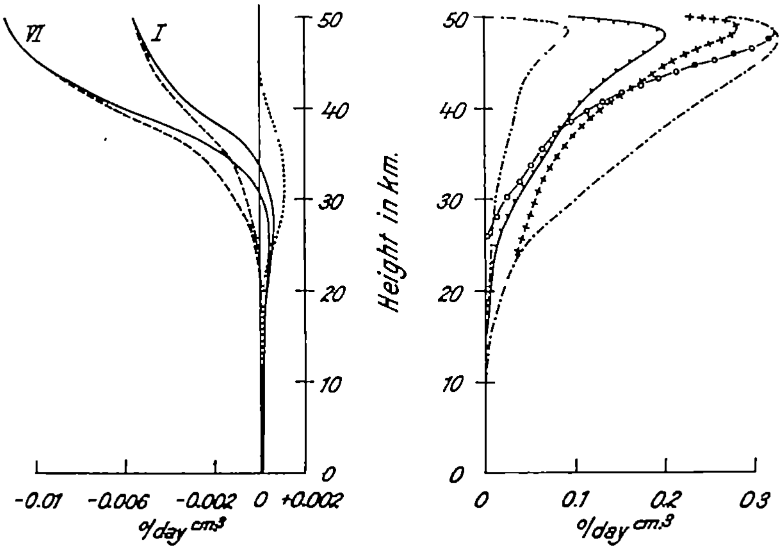

FIG. 1. Left. Cooling effect as affected by long-wave radiation. Two examples for different temperature distribution in the stratosphere are shown. Nocturnal radiation ———. Ozone radiation — — —. Terrestrial radiation . . . . . .
Right: Heating effect as affected by absorption of solar radiation. March 21 + + + + June 22 — · — · — · September 23 ┬┬┬┬┬ December 22 — · · — · · — · · Ultra-violet absorption only (for June 22) —o—o—o

The results are shown in Fig. 1. It is seen that the heating effect is about ten times the cooling effect at a height of 50 km. Below 25 km. no remarkable influence could be found. Despite the fact that the centre of gravity is situated at 25 km., the maximum lies at 50 km. This demonstrates the importance of an exact determination of the ozone concentration in the highest layers. The maximum corresponds to many assumptions on the constitution of the upper atmosphere.

The results summarized here will be published elsewhere in a more detailed account of these and other phenomena concerning atmospheric ozone.

Value of the Acid Silver Nitrate Reaction as a Test of Ascorbic Acid

SZENT-GYÖRGYI observed that the suprarenal cortex reduces silver nitrate, and attributed this property to the ascorbic acid (vitamin C) which it contains[1]. Many workers have observed that this reaction disappears in scurvy and comes back if ascorbic acid is given to the scorbutic animal[2]; the reaction was also used for histological detection of vitamin C, and, the specificity of silver nitrate being increased by acidification with acetic acid, an accurate cytological study of its repartition could be made[3].

The value of the silver nitrate reaction as a test of ascorbic acid has been questioned. Harris and Ray[4], noticing that the liver and the suprarenal medulla, though rich in ascorbic acid, failed to be coloured by silver nitrate, concluded that the absence of this reaction was very little guide as to the presence or absence of vitamin C. Many investigators consider the reaction valueless[5,6]. For example, in a recent review of the question[7], King says: "Silver nitrate staining is not reliable qualitatively or quantitatively as an index of vitamin C in tissues."

In order to clarify this question, we have to consider:

(1) *The occurrence of a reaction with acid silver nitrate.* The reduction of this reagent, without any action of light or heat, is a very specific test of ascorbic acid for the following reasons: the marked reductions are observed only in the organs which by the chemical and biological methods appear to be rich in ascorbic acid (suprarenal cortex, corpus luteum, interstitial cells of the testis and anterior pituitary). In these organs, the cells appear filled with the granules of reduced silver. In organs poor in ascorbic acid, a slight reaction, frequently with a deposit of the silver precipitate at the Golgi apparatus (suprarenal medulla, epididymis), or no reaction except along the walls of the blood vessels, is observed.

When large quantities of ascorbic acid are given to a guinea pig, new reactions appear in the epithelial cells of the intestine, and in the convoluted tubules of the kidney, corresponding chiefly to the increase in absorption and elimination which can be demonstrated by chemical methods.

If guinea pigs are given a diet without ascorbic acid, the reactions disappear quickly, so that after ten days none can be observed in their organs. Biological experiments confirm the absence of ascorbic acid in these conditions.

If ascorbic acid is injected into a guinea pig which is scorbutic and therefore depleted of its reserve, all the reactions reappear within a few hours after the injection.

It may be concluded that all the reactions observed after action of acid silver nitrate are due to ascorbic acid, and, as the histological localizations of the reactions are exactly the same in the animals which, like the rat, are able to synthesize ascorbic acid and therefore cannot be depleted of it, it is logical to assume that in these animals, too, these reactions are caused by ascorbic acid.

However, there is one exception: the melanin granules in the Langerhans cells and the Malpighian layer of the skin show a reaction which may not be attributed to ascorbic acid, since it persists after methyl alcohol extraction, and does not disappear in the scorbutic guinea pig. This single exception ought not to cause confusion because of the easily recognizable pigment granules.

(2) On the other hand, *the absence of reaction* with acid silver nitrate may indeed be observed in some tissues rich in ascorbic acid (suprarenal medulla, liver . . .), so that a negative result must not be necessarily interpreted as indicating the absence of ascorbic acid.

The chief reason for this failure to reduce silver nitrate is the presence in the organs of factors inhibiting the reduction of ascorbic acid; these 'inhibiting factors' have been described by Huszak[8] in the suprarenal medulla and by de Caro and Giani[9] in other tissues.

In short, the absence of a coloration by acid silver nitrate does not necessarily mean the absence of ascorbic acid, but a positive reaction is a very specific test for this substance.

Kerr Constants of the Hydrogen Halide Gases

ON the basis of a recent note dealing with the polarization ellipsoids of the hydrogen halide gases[1], it becomes possible to calculate their Kerr constants (Na–*D* line, 20° C., 760 mm.), numbers which should be directly capable of experimental verification.

We take the Boltzmann constant $k = 1{\cdot}371 \times 10^{-16}$ erg per degree per molecule, $T = 293°$ K., $\pi = 3{\cdot}1416$, $N = (6{\cdot}064 \times 10^{23} \times 273)/(22{,}414 \times 293) = 2{\cdot}522 \times 10^{19}$, and $\Delta_{\text{HX}} = 0{\cdot}0119$. Further experimental and estimated constants, different for the four halides, are taken as follows:

Di-atom	n_{D}	n_{∞}	μ	b_1	b_2
HF HCl HBr HI	1·000140 1·000446 1·000612 1·000919	1·000136 1·000435 1·000594 1·000883	$1{\cdot}58 \times 10^{-18}$ 1·06 0·80 0·41	$0{\cdot}96 \times 10^{-24}$ 3·07 4·19 6·24	$0{\cdot}72 \times 10^{-24}$ 2·30 3·14 4·68

The following relations are applied[2]:

$$K_1 = \frac{2\pi N}{15kT}\left[(b_1 - b_2)^2\,\frac{n_{\infty}^2 - 1}{n_{\text{D}}^2 - 1}\right] = 2{\cdot}629 \times 10^{32}\left[(b_1 - b_2)^2\,\frac{n_{\infty}^2 - 1}{n_{\text{D}}^2 - 1}\right] \quad . \ (1)$$

$$K_1 = \frac{3\,\Delta}{2\pi kNT(6 - 7\,\Delta)}(n_{\infty} - 1)(n_{\text{D}} - 1) = 9{\cdot}477 \times 10^{-8}(n_{\infty} - 1)(n_{\text{D}} - 1) \quad . \ (2)$$

$$K_2 = \frac{2\pi N}{15k^2T^2}\mu^2\,(b_1 - b_2) = 6{\cdot}545 \times 10^{45}\,\mu^2\,(b_1 - b_2) \quad . \ . \ . \ . \ . \ (3)$$

$$K = K_1 + K_2 \quad . \ . \ . \ . \ . \ . \ . \ . \ . \ . \ . \ . \ . \ . \ . \ . \ (4)$$

where the symbols have their usual significance.

The value of K_1 by (1) is probably more accurate than by (2), and is independent of the result Δ_{HX} = a constant. As an approximate check on the theory by which these numbers are derived, however, the value of K_1 by (2) is substituted in (1) to obtain a calculated value of $b_1 - b_2$, for comparison with that derived from the estimated b_1's and b_2's given above. Comparison of the last two columns of the following scheme shows the general run of the numbers to be in agreement.

Di-atom	K_1 by (1), K_2, K ($\times 10^{15}$)			K_1 by (2)	$b_1 - b_2$ ($\times 10^{24}$)	
					est.	calc.
HF HCl HBr HI	0·015 0·152 0·281 0·615	(3·922) 5·662 4·399 1·717	(3·94) *5·81* *4·68* *2·33*	0·018 0·184 0·345 0·769	0·24 0·77 1·05 1·56	0·26 1·18 1·16 1·96

K_{HCl} agrees closely, as expected, with the experimental value $5{\cdot}75 \times 10^{-15}$ (Hansen[2]). The constants for other wave-lengths can be estimated by this method as required.

It is noteworthy that HCl appears to have the highest constant in the group. As, however, K_2 is very sensitive to changes in μ, this may not be significant. If μ_{HF} were as large as 2·0 (Smallwood[3]), $K_2 = 6{\cdot}282$, $K = 6{\cdot}30$, making the gradation continuous from HF to HI.

The present results appear to support the theory put forward in the former communication[1].

The 2·73μ Absorption Band in Fused Silica

LYON and Ellis in a recent note[1] refer to the absence of the 2·73 μ infra-red absorption band in specimens of fused silica examined by them, and suggest that the band found at this wave-length by previous investigators may be due to an impurity, possibly CO_2 or H_2O.

It is certainly unlikely, as I have previously pointed out[2], that it can be due to vitreous SiO_2, since the absorption coefficient at the centre of this band was widely different in specimens examined by Parlin[3] (K = 0·52), Dreisch[4] (K = 0·33) and me[5] (K = 0·03) and, further, crystalline quartz shows no trace of such a band whilst every other band in fused silica between 1 and 7·5 μ has its counterpart in the crystalline quartz spectrum.

Fused silica, in the course of manufacture, comes in contact with hot carbon and reacts with this with the evolution of gas. This makes contamination with CO_2 seem likely, and the band in question does fall in the centre of the region of CO_2 absorption at about this wave-length[6]. This suggestion is open to the criticism that the next strong CO_2 band, that at $4{\cdot}28\,\mu$, is definitely absent from the fused silica spectrum and that the $2{\cdot}73\,\mu$ band is single and broad while the corresponding structure for gaseous CO_2 appears as two doublets under similar resolving power. Nevertheless, solution of CO_2 in a solid may radically modify its absorption spectrum.

Another possibility is that the band may be due to another crystalline modification of silica, that is, a cristobalite or tridymite. This seems unlikely as in readings taken on the same set of specimens during one or two years no ageing effect was detected, and further, of specimens cut from one initial melt, some were used immediately without additional heat treatment while one was re-melted to improve its optical homogeneity without any significant difference being introduced in the intensity of this band in the material. A very slight difference was observed between different initial melts in this respect. It would be of interest to know whether the specimens examined by Lyon and Ellis were prepared without contact with carbon, as if this was the case the theory of the CO_2 impurity is decidedly strengthened by their result.

African Honey Bees

SKORIKOW[1] has published a map showing the distribution of the three main types of ordinary honey bees, *Apis mellifera* L., occupying the Palæarctic region, *A. indica* Fabricius, the Oriental, and *A. adansoni*, Latreille, the Ethiopian. Madagascar is inhabited by still another form, *A. unicolor* Latreille. Alpatov, of the University of Moscow, has published statistical studies of South African honey bees, separating two races, called *A. adansoni* and *A. unicolor*, the latter being the form with black abdomen and scutellum. But his *A. unicolor* came from near Cape Town, and were surely not the true *unicolor*, but the race which Buttel-Reepen (1906) named *intermissa*. This insect differs from *A. unicolor* in having bands of tomentum on the abdomen, these being usually conspicuous, but sometimes not evident, when the specimens are worn, or the abdomen is much contracted.

I have just examined the honey bees of the 1933–34 expedition by Mr. and Mrs. J. Ogilvie to South Africa, and I find eight *A. adansoni* (from Bot River, Belmont, Kirstenbosch, Upington and Seeheim) and fifteen *A. adansoni intermissa*, from Lions Head, Cape Town and from Bot River, but the majority from an uncertain locality, owing to a mistake in labelling at the British Museum. From the expedition of 1931, I find four specimens from Victoria Falls, which I had overlooked. Three are ordinary *A. adansoni*, but of two collected by my wife on Livingstone Island, one is *A. adansoni*, and the other, abruptly different, is to all appearances *A. unicolor*, though the surface of the abdomen is duller than in a specimen from the Seychelles Islands.

No doubt the African bees are being crossed with different forms of the European species, introduced by man; hence it is desirable that material should be collected as soon as possible in all parts of Africa and deposited in the British Museum or elsewhere, where it will be available for minute statistical studies, such as those of Alpatov. Enderlein, in his revision of *Apis* (1906) distinguishes the African forms by the smaller size (body 10–12 mm. long, 3½ mm. broad, front wings 8–9 mm. long) and then divides them into those with black abdomen (*unicolor* and *intermissa*, as just given, and also a form *friesei*, Buttel-Reepen, differing from *intermissa* by the average smaller size and the yellowish-brown scutellum), and those with a largely fulvous or yellow abdomen, the true *adansoni*, closely resembling the familiar Italian race. The variety *friesei* comes from Mombasa, East Africa.

Vernalization

THE phenomenon of 'vernalization', namely, the acceleration of ear formation in winter varieties of cereals by exposing the germinating seed to low temperature, is now well known[1]. The underlying cause of this effect of low temperatures is by no means clear. Enzymatic changes in the fruit external to the embryo have been postulated by Richter and others. Experiments to test such possible changes or hormone effects have been performed by Krasnoseljskaja-Maxomova in which endosperm of winter and spring varieties has been interchanged. Similar experiments have been repeated by Sereiskii and Sluckaja, and interchange of embryos has also been tried. The former investigator claims positive results which, however, the latter investigators failed to substantiate.

Experiments recently carried out by us have shown conclusively that excised embryos separated completely from the endosperm and grown on agar containing 2 per cent glucose and mineral nutrients alone can nevertheless be vernalized in the same way as complete 'seeds'. Such separated embryos kept at 1° C. for six weeks and then planted out produced normal plants earing ten weeks later, whereas similar embryos kept at 18° C. until they had reached the same stage in development (coleoptile developed, but first leaf not emerged) showed no signs of 'shooting' after a further ten weeks of growth.

It would appear therefore that the 'cause' of vernalization by low temperature is entirely inherent in the embryo, and is not dependent in any way on the metabolism of the endosperm or aleurone layer.

[1] Vernalisation and Phasic Development of Plants. Bull. 17 Imperial Bureau of Plant Genetics.

Points from Foregoing Letters

IN further development of her working hypothesis of protein structure, according to which a network ('cyclic') structure is postulated in place of the branched chain ('polypeptide') structure, Dr. D. M. Wrinch calculates the approximate energy of formation of 'cyclol' molecules from polypeptides. The calculations suggest that the process of linkage is facilitated if the appropriate groups are in the imide form, —C(OH)=N—, a state which may be brought about by the action of certain enzymes. F. C. Frank, commenting on Dr. Wrinch's theory, estimates the energy balance in the process and, to account for the deficiency in the necessary energy, postulates the existence of an additional source of energy similar to that provided by the strain in the side-chain cross-linkages found in keratin. He further points out that hydration also provides part of the necessary additional energy, and helps in explaining certain properties of the proteins, observed in 'degeneration' and 'denaturation'.

Criticizing Prof. Hale Carpenter's description of the behaviour of the African insect *Charaxes*, Prof. H. E. Armstrong states that an insect cannot *deliberately* hide itself, and suggests that 'mimicry' may be caused by changes in food, temperature, or by hybridization. In reply, Prof. Hale Carpenter gives further examples of *deliberate* action and of mimicry which cannot be explained by the factors suggested by Prof. Armstrong.

Indications of the occurrence of earthquakes and of accompanying seismic sea-waves (tsunamis) in Ordovician times (Caradog age) are described by Dr. A. Lamont, from observations of strata in the Irish Free State. These may involve revision in the interpretation of certain features, such as crush-conglomerates and intrusive tuffs, the origin of which has hitherto been ascribed to other agencies.

Miss H. D. Megaw and Prof. F. Simon have determined the approximate values of the density, compressibility and thermal expansion of ordinary and heavy hydrogen (deuterium) in the solid state (at 4·2° K.), by comparison with helium, in order to show the influence of the 'zero point energy' (inferred from Planck's second quantum theory) on those properties.

Part of the oxygen consumed by certain luminous bacteria (*Photobacterium phosphoreum*) is apparently directly connected with the amount of light emitted. K. L. van Schouwenburg and J. G. Eymers find that, at 16° C., about 500 molecules of oxygen are used per quantum of light emitted, but the efficiency of the light-emitting process varies with conditions.

Some further notes on the behaviour of and variations in the ionized *C* layer of the atmosphere (5–30 km. high) are given by Prof. R. C. Colwell, A. W. Friend, N. I. Hall and L. R. Hill. The authors explain the weakening of the radio signals from the stratosphere balloon *Explorer II*, when it passed through the 20 km. level, as due to its having reached the top of the *C* layer; a portion of the radio waves would then be reflected outwards into space, instead of being reflected towards the earth.

Of the two optically active forms of nicotine, Dr. G. A. Gause finds that the lævo-form has a greater inhibition power upon the fermentation of glucose by various microbes than the dextro-form. Oxidation processes on the other hand are more strongly inhibited by the dextro-rotatory nicotine. The author also finds differences in the action of the two optically active nicotines upon similar processes taking place in green Algæ and in various animals.

Formulæ for the magnitude of interaction between neutrons and protons (via particles of small mass—positrons and neutrinos) have been worked out by D. Iwanenko and A. Sokolow, with simple scalar equations of the type of Schrödinger's second order relativistic equation. The process is supposed to be somewhat on the lines of electromagnetic interaction.

Mrs. A. Vnukova finds that the antagonistic action exerted by light of certain wave-lengths, which weaken the latent image on a photographic plate ('Herschel effect'), is more effective in the presence of oxygen and becomes negligible in nitrogen or carbon dioxide.

From the difference between the energy absorbed by ozone from sunlight during the day, and that lost by radiation during the night, allowing for the absorption of radiation from the earth and from other layers, R. Penndorf calculates the heating effect due to the presence of ozone in various layers of the atmosphere. The calculations indicate a maximum heating effect at a height of 50 km. where the heating is about five times the cooling effect.

Having investigated the conditions under which silver nitrate can be relied upon as a test for vitamin C (ascorbic acid), A. Giroud and C. P. Leblond conclude that while the absence of a coloration by acid silver nitrate does not necessarily mean the absence of ascorbic acid, a positive reaction, with few exceptions, is a specific test for this substance.

In a test of the theory of the polarization ellipsoids of the hydrogen halide gases, Dr. C. H. Douglas Clark and Dr. E. C. Humphries have estimated the constants *K* for these gases occurring in the Kerr (magneto-optic) effect. These numbers are capable of experimental verification, and appear to confirm the theory.

In explanation of the origin of the absorption band (wave-length 2·73 μ) in the infra-red spectrum of certain specimens of fused silica, Dr. D. G. Drummond favours the suggestion that it is due to the presence of carbon dioxide, with which the silica may readily become contaminated during the process of manufacture.

With reference to the various forms of African bees described, Prof. T. D. A. Cockerell records several specimens of *A. adansoni* and *A. adansoni intermissa*, and one specimen of *A. unicolor* in the British Museum collection. He directs attention to the desirability of collecting further material for genetic studies before the African bees become crossed with different forms of European bees introduced by man.

Dr. F. G. Gregory and O. N. Purvis have carried out experiments with embryos of cereals separated from the rest of the seed and grown on agar (containing 2 per cent glucose and mineral salts) kept near the freezing point (1° C.) for six weeks and then planted out. They find the same subsequent acceleration in the ripening process (vernalization) as in the case of whole seeds similarly treated, which indicates that the cause of 'vernalization' is inherent in the embryo.

Research Items

Physical Characters of the Bedouin

DR. WILLIAM M. SHANKLIN, of the American University of Beirut, in the summer of 1934 made an expedition into the Syrian desert with the object of studying the members of the Rwala tribe, who appear to conform to the definition of a Bedouin as "a nomad who breeds and keeps camels and . . . able to trace his descent from certain recognized pure-bred Bedouin tribes". The Rwala are a subdivision of the Al-Glas, one of the major branches of the Anazeh nation, who are found more especially in the Hejaz and Syrian deserts. In recording his results (*J. Roy. Anthrop. Inst.*, 65, Pt. 2; 1935), Dr. Shanklin summarizes the evidence of the blood-groups, published more fully elsewhere, as showing a high percentage of blood group *O*, indicating that the Bedouin belong to a race of very considerable antiquity. The American Indians also belong to the blood-grouping *O*. The Rwala in their physical characters have retained features which are regarded as having characterized the primitive Mediterraneans; but elsewhere in the Near East, Egypt, Arabia, etc., this type has been overrun by the brachycephalic element, to which observers have directed attention. Thus among their average measurements are: head-length, 191 mm., breadth, 144 mm.; cephalic index, 75 (range 67 to 82); nasal height, 55 mm., nasal breadth, 35 mm.; bizygomatic breadth, 130 mm.; bigonial breadth, 106 mm. They are white, but have brown, or brunet skin, straight black, or brown, hair, brown eyes and high, straight, narrow noses. If the view that holds that the agglutinogens *A* and *B* are of relatively late origin is accepted, the evidence of the blood-groups would corroborate the evidence of physical character in showing that the Bedouin may well be representatives of the primitive Mediterranean race, who have preserved their racial character over a long period. On the other hand, the earliest known skulls of the American Indians, as pointed out by Hooton, are also dolichocephalic, and this, with their blood-grouping, accepting the conclusion of their Asiatic origin, may point to the fact that they and the Bedouin are the descendants of a remote, but common, primitive stock.

New British Bird

THE rather remarkable number of scarce American birds that have appeared in the British Isles in the past two years—yellowshank, American pectoral sandpiper, and others—is further increased by the recent addition to the British list of Audubon's little shearwater (*Puffinus assimilis-l'herminieri* Leason) which J. J. Harrison describes in the July issue of *British Birds* as of the West Indies form. The bird was found alive on the beach at Bexhill-on-Sea by Mr. W. E. Dance on January 7, being mobbed by gulls. When taken home it soon collapsed and died. The record is of importance because Gould recorded a specimen from Dover, but owing to insufficient verification it was never accepted, and he himself excluded it from his later works on British birds. It was in the April issue of *Ibis* that Mr. W. P. Lowe described another new British bird, the Franklin's gull, which was watched among a flock of herring and black-headed gulls on Exmouth beach, Devon, on January 19, 1936. The British razorbill has recently had its status as a separate sub-species established owing to comparisons of British with Swedish and Greenland skins showing that the British birds are definitely smaller in measurements than the Continental ones and that the Faroe birds belong to the British race; hence the alteration in nomenclature to *Alca torda britannica*.

Periodicity in Algæ

IN certain districts of India, the regularity of the seasonal changes, especially as regards temperature and rainfall, offers an opportunity for the study of algal periodicity which would never arise under the variable conditions of the English climate. M. S. Randhawa (*Proc. Indian Acad. Sci.*, 3, No. 5, 1936) has now followed the periodicity of the freshwater Algæ in the Saharanapur District over the greater part of two years, and has obtained some very definite results. Many of the Algæ rest through the hot dry summer months in the form of thick-walled oospores; these germinate with the rain of the Monsoons and continue to grow vegetatively through the cooler autumn and winter months. With the rise of temperature in the spring a period of sexual reproduction sets in, ending with the production of thick-walled oospores. The gradual rise in temperature after a long period of vegetative growth is evidently particularly favourable to sexual reproduction, which is apparently strikingly prolific. Under these more consistent climatic conditions, the Algæ fall into step with the seasons and thus show marked periodicity, which is masked in more variable climates by small changes which affect the algal growth. It is of interest that the filling up of the ponds and streams by flood waters after the dry season is accompanied by a peak in the development of Myxophyceæ, an effect which has also been recorded in British Lake District waters when much debris is carried down by heavy rain.

Electric Heating of Garden Frames

A PAPER by Dr. J. Grainger and T. F. Armstrong (*Gardeners' Chronicle* of June 13 and 20) shows that the use of soil heating by buried electric cable is quite satisfactory for raising seedlings of green crops such as lettuce and endive, for the forcing of special crops, as mint and rhubarb, but not for root crops such as radishes, which tend to flower rather than to swell their roots in heated soil. A valuable table showing detailed consumption of electricity for raising the soil temperature by varying amounts is given. Heating cables have also been used to heat the air within deep propagating frames, and although this was successful from a horticultural point of view, it requires an average of 1·06 units of electricity per cubic yard per day to raise the temperature 10°–15° F. above that outside the frame. With electricity at ½*d.* per unit, this works out about twice the cost of heating similar structures by a coke fire in a hot-water system. The paper also shows that heating the soil may aggravate the effects of crown rot disease of rhubarb, during forcing.

Autopolyploidy

THE evolutionary significance of autopolyploidy, based on the numerous cases now investigated, has been considered by Dr. A. Muntzing (*Hereditas*, 21, 263). About one hundred species are now known to show intra-specific variation in chromosome number, autotetraploidy being the most common condition. Such tetraploids usually show *gigas* characters, being generally stouter and slower in development. Both morphological and physiological changes result from the larger cells, but hexaploids frequently and octoploids generally show dwarfing, indicating that the optimum chromosome number has been exceeded. Intra-specific tetraploids are also ecologically different from the diploids, and they usually have a different geographical distribution, being generally, but not invariably, more northern. Such polyploids appear to be generally more hardy and adapted to a northern, alpine, xerophytic or coastal habitat, into which the corresponding diploid does not extend. Experimentally induced autotetraploids show essentially the same features as natural ones. Chromosome association at meiosis is the same in both, ranging from almost complete bivalency to almost complete quadrivalency. Wild autopolyploid races are usually fertile, while experimentally induced ones generally show poor fertility. This difference may be accounted for by the effects of natural selection. The perennial species in a genus have a higher average chromosome number than the annuals. Autopolyploidy has played an important role in the evolution of higher plants.

Tokyo Earthquakes in 1935

WE have received the last of the quarterly *Seismometrical Reports* for 1935 issued by the Earthquake Research Institute. These refer only to earthquakes that were sensible in Tokyo. After the great earthquake of 1923, a system of eight seismological stations was founded in and around Tokyo. During the year 1924, 60 earthquakes were felt in Tokyo, and the records obtained were sufficient to determine the epicentres of 52 and the focal depths of 42 earthquakes. In 1935, the number of stations had risen to thirteen, the number of sensible shocks was 78, the epicentres of all and the focal depths of 67 earthquakes were ascertained. In Tokyo itself, most of the shocks (55 in number) were just perceptible, and none at any station reached even semi-destructive strength. The mean depth of the foci was 28 miles, the greatest depth measured being 75 miles.

Oxidation-Reduction Potential

COMPARATIVELY few accurate measurements of the potentials of oxidizing-reduction systems have been made, one of the main difficulties being the ease of hydrolysis usually observed with the higher valency ion. One of the best investigated systems is that of the thallic and thallous ions, $Tl^{\cdots}/Tl^{\cdot}$, which was investigated in 1905 by Abegg and J. F. Spencer. Later investigators showed that the potential appeared to vary considerably with the nature of the anion, doubtless owing to the formation of anion complexes. Two recent investigations of the electrode, by J. R. Partington and H. I. Stonehill (*Trans. Faraday Soc.*, 31, 1357; 1935) and by A. A. Noyes and C. S. Garner (*J. Amer. Chem. Soc.*, 58, 1268; 1936), have included precautions to avoid this effect. The former investigators used the sulphates in sulphuric acid solution, and the latter the nitrates in nitric and perchloric acids. The two values for the normal potentials, 1·20–1·22 volts, and 1·230 volts, respectively, are in satisfactory agreement. Since there is little likelihood that complexes are present in the nitrate and perchlorate, the results show that the formation of sulphate complexes by thallic sulphate is not very extensive. An interesting feature of the work of Noyes and Garner was the use of ozonized oxygen for the oxidation of the thallous to the thallic salt in concentrated nitric acid, thus avoiding the introduction of extraneous substances into the solution.

Experiments with Neutrons

C. H. COLLIE and J. H. E. Griffiths (*Proc. Roy. Soc.*, A, 155, 434) have investigated the absorption of fast and of slow neutrons using an arrangement in which the effect of mere scattering was largely eliminated. The absorption cross-sections for fast neutrons were nearly the same ($1–1·5 \times 10^{-24}$ cm.^{2}) for a number of elements tried. The experiments with detectors sensitive to slow neutrons showed an increase in activity when the absorber was put in, and this probably means that new slow neutrons were produced by collision of the fast neutrons with the absorber nuclei. S. Kikuchi, H. Aoki and K. Husimi (*Proc. Physic. Math. Soc. Japan*, 18, 115) have studied the production of γ-rays from numerous substances bombarded by fast neutrons (2×10^6 e.v.). Slow neutrons were excluded from the specimen. The cross-sections calculated for γ-ray production vary unsystematically with atomic number, the absolute values are of the order 5×10^{-25} cm.^{2}, and it seems that γ-ray production is responsible for a considerable part of the absorption of fast neutrons by many elements. The γ-ray energies seem to be fairly similar in all cases, but they are not monochromatic. The γ-rays excited by slow neutrons appear to be of a different type, they are usually harder, and are to be ascribed to the capture radiation associated with nuclear transformations.

Statistical Research Memoirs

THE first volume of a new publication entitled *Statistical Research Memoirs* appeared in June of this year, edited by Prof. E. S. Pearson and Dr. J. Neyman, and published by the Department of Statistics at University College, London. The *Memoirs* will contain only papers prepared in that Department. The series will not be strictly periodical, but it is hoped that a volume of more than 150 pages will be issued about once a year. The price is 15*s.* a volume, or 12*s.* 6*d.* to those who signify in advance their intention to purchase the next volume. The *Memoirs* are intended to advance the general theory of statistics, which at present is not yet on firm foundations. It is the ambition of the Department to contribute towards the establishment of a theory of statistics on a level of accuracy which is usual in other branches of mathematics. The present volume contains seven papers, two by J. Neyman and E. S. Pearson, and the others by P. P. N. Nayer, B. L. Welch, P. O. Johnson and J. Neyman, P. V. Sukhatme, and R. W. B. Jackson. All of these deal with closely related subjects, connected with the well-known methods of Neyman and Pearson for testing statistical hypotheses. The *Memoirs* will, as a general rule, be restricted to the general theory. Papers dealing with the applications of statistics serve their purpose best when they appear in journals devoted to the particular fields of application.

Forestry in Kenya

THE annual forest report for 1934 for the Colony and Protectorate of Kenya (Nairobi: Government Printer, 1935) is of interest on the subject of reservation of forests. The total reserved forest area in 1921 was 3,207 square miles; in 1934 it amounted to 4,711 square miles. During this period, some areas of reserve forest have been given up.

From the report, the reasons for giving up areas of forest already reserved is not clear. The common reason for such returns to the Civil Department is that the land is required, and can be more profitably used for, agriculture. This is not given as the reason in Kenya. The Conservator writes: "In making these excisions from the forest very careful consideration is given to each case, and no land that is thought to be of value to the forest, climatically or commercially, is given up". It is somewhat difficult to visualize the uses to which land of no value to the Forest Department can be put. In spite of this statement and the admission that there is a certain amount of anxiety in the Colony as to the adequacy of the forest area, "and a feeling that this area is being seriously diminished by constant excisions", the report states that, during the year, the Kenya Land Commission recommended that approximately 13,500 acres should be excised from forest reserves in settlement of various claims. The Department considers that "little real damage was done"; but the Commission itself records in its report that "We agree with the conclusion that the items shown in the schedule [that is, the land that was surrendered] should be regarded as the limit of sacrifice which the forest should be required to suffer".

This appears to be strange reading. In the administration of a country, nowadays, a clear understanding of the position played by the forests, both economic and climatic, should be possible and form part of the policy of governance. Either the forest is required to fulfil these vital interests of the population or it is not. Once the maintenance of the water supplies of a country, provision for local requirements of the population, and such commercial interests as may be considered advisable to provide for have been arranged, the rest of the forests may be sacrificed, in other words, felled and suffered to disappear with equanimity in the interests of other and more serviceable utilization of the land. But such disposal of the land does not and should not entail "the limit of sacrifice which the forest should be required to suffer". It would appear in Kenya that, for some reasons not apparent in the report, land previously forming forest reserves is being alienated at some danger to the maintenance of a correct proportion of forest, even though there appears to be some 800–1,000 square miles still to reserve, lying mainly within the native reserves of Meru, Masai, Cherangani and Marakwet.

The cuts in expenditure account for much during the last few years; but in view of the fact that there has been an expert forest service in Kenya for some considerable period, it is depressing to read that "it was still impossible to detail an officer or officers for the special work of enumerations and compilation of working plans; divisional staffs cannot be expected to make much progress in such important work".

The chief work in connexion with regenerating the forests is by exploiting the forest produce indigenous to the areas it is desired to plant, and then, by means of controlled shifting cultivation or *toungya*, replanting suitable trees in regular plantations. In such work, as the report states, definite plans are required. But plantations will not replace square miles of indigenous forest, even if they are putting back a greater potential tonnage than that of the present annual cut. To know what is standing in the forests should be the vital factor antecedent to exploitation. Until this factor has been ascertained, it appears irrelevant to consider markets available for export.

Rural Custom in Civilized Communities

IT is an interesting coincidence that the claims of ancient custom and conservatism in civilized communities as worthy of observation and record should be urged almost simultaneously from three different sources, of which one is far removed from the other two—England, France and South Africa.

Mr. R. U. Sayce in *Man* of April, emphasizing the importance for anthropology of the study of civilized, as well as uncivilized, peoples, refers as a case in point to the remarkable variety shown in British agricultural implements in response to local conditions and requirements. Not all, indeed, are of British origin. Some have been introduced by foreign workmen, as, for example, the implements used in cutting peat near Manchester and the implements of the sugar-beet industry, both of which are of Dutch origin. The bill-hook affords an interesting example of this variation. Mr. Sayce figures no less than forty-eight distinct varieties of the bill-hook, all of which are now manufactured, and are in use, in different parts of England and Wales. That Mr. Sayce is not entirely ploughing a lonely furrow is indicated by the fact that in the same month of April a collection of implements illustrating the changes in agriculture during the last hundred years was presented to the Colchester and Essex Museum.

Apart from its cultural value, the study of traditional types of agricultural implements may have a distinctly practical bearing on the work of the archæologist in affording a clue to the character and purpose of a find of unusual or previously unknown type. This latter function of the study is stressed by M. L. Franchet in an introductory sketch of agricultural ethnography (*Revue des Sciences*, 111, April

11, 1936), in which he dwells on continuity in type as a regional characteristic. Analogies to archæological finds, he points out, have been sought among primitive peoples, geographically remote, and often have led to erroneous results; whereas investigation in the area in which they were found, among the people of to-day, would have revealed in many instances the identical type, or a derivative, in everyday use. M. Franchet himself has interpreted his archæological finds by this method with illuminating effect, and he has also traced modern implements back to their origin in the bronze age. His researches in the forest of Montmorency find an ancestry for certain implements which leads back to the stone age, while the equipment of viticulture and wine-making goes back, with the industry, to Gallic times, though, of course, not all the implements in use are of an equally remote origin. There is a pregnant reminder that the conversion of the sword into a ploughshare is more than a rhetorical trope in the observation that in primitive conditions the weapons of war do become the implements of peaceful occupations when hostilities cease.

A legitimate pride of descent and a half-humorous, but wholly determined, practice of traditional ways of doing certain things is attributed to the Cape population of Dutch descent in a record of surviving customs by Eric Rosenthal ("Old Time Survivals in South Africa". Government Printer, Pretoria, 1936. Pp. 38). The survival of so much that, on a superficial view, is obsolete may seem remarkable in a community that is now essentially up to date, and of which some of the industries are highly mechanized. To some extent this may be due to a racial pride and race consciousness; but the real explanation lies deeper. It is part of an enduring environmental adaptation. The clue is afforded by the survival of the old ox-wagon, virtually unchanged since its first introduction from Holland by Jan van Riebeck in 1632, except for the addition of a brake in the eighteen-sixties, yet of which there are more than a hundred thousand in use in South Africa side by side with the automobile. This apparent anomaly may be explained by the fact that the ox wagon has been the efficient cause in the development of the characteristic South African civilization. When built in the traditional way and from the traditional materials, it is still the best, and indeed the only, means of transport which is fully adapted to the geographical conditions and the social and economic needs of the country. One useful feature of ox-wagon travel, the 'outspan' for night camping, still found in every community, serves both the old and the modern need in a country where distances are great and hotel facilities few.

Empire Surveys

FORMERLY it was difficult for surveyors, more or less isolated in the Dominions and Colonies, to keep in touch with the advances in technique which are constantly occurring both as regards instruments and methods, cut off as they are from their fellow surveyors.

The institution of periodical conferences, held in the heart of the Empire, under the auspices of the Colonial and War Offices, has changed all this. Surveyors from different parts of the Empire meet and get in touch with each other as they never did before. Nothing but good can result from this. There has also been established a quarterly journal, the *Empire Survey Review*, devoted to survey technique and the discussion of matters of interest to the surveyor. At last year's conference, all the Dominions (except New Zealand), India and Colonies possessing survey departments, were represented, as well as many British scientific societies and universities.

At the conference, the report of which has lately been published*, some forty papers bearing on all branches of surveying and dealing with the latest instrumental developments were read and discussed. Of these, no less than eight dealt with matters connected with air survey, showing the importance now attached to this branch of the subject.

From such a mass of matter it is not easy to single out for notice particular subjects. Major M. Hotine has an interesting paper on signals for triangulation. Sufficient attention is not always paid to signals where accurate work has to be done. As the author points out in the case of opaque signals made of wood, it is very necessary in order to avoid warping and the movement of the signal due to the drying of material after erection, that they should be made of seasoned timber, instead of, as is usually done, from wood cut on the spot. Incidentally, Major Hotine points out that if primary triangulation is undertaken at all, it should be of first-class order and not "only good enough for immediate purposes". Someone is sure to want to extend it in the future, in which case it may have to be done all over again. Therefore every precaution should be taken with the observations, the best instruments should be used and suitable signals well centred over the marks, or the work will not conform with first-class triangulation. A new type of electric night projector is being brought out by Messrs. Cooke, Troughton and Simms, Ltd., which can be worked by a 12-volt accumulator such as is carried on a motor car. We understand it is being used by the Ordnance Survey in the retriangulation of Great Britain now in progress.

Many papers are read chiefly with the view of encouraging discussion. For example, a new instrument is experimented with; it is of considerable advantage to know what the experience of others has been with an instrument of the kind. When we consider how grudgingly money is allotted for survey purposes in Great Britain, it is astonishing to read that more than £6 per acre is spent on the survey of Georgetown and Malacca in the Federated Malay States. The value of survey out there is evidently known and appreciated.

Perhaps one of the most remarkable papers read before the conference was by Lieut. E. H. Thompson, R.E., on "An Automatic Plotting Machine for Air Photographs". This machine is from the designs of Mr. Fourcade, who has been working at this difficult problem for some years. Lieut. Thompson has constructed a most ingenious model from Meccano to illustrate the working of this complicated instrument. Without something of the sort, it is very difficult to understand how it functions.

---

* Conference of Empire Survey Officers 1935. Report of Proceedings. (Colonial No. 111.) Pp. vi+377+36 plates. (London: H.M. Stationery Office, 1936.) 20s. net.

Brigadier MacLeod pleads for the co-ordination of African surveys. He points out that some kind of arrangement should be come to among the various nations possessing African territory with the view of adopting uniformity of scales and projection of maps, before it is too late. So far, this has been achieved only in the case of the International "Carte du Mond" on the 1/1,000,000 scale. He also urges the adoption of the metric unit. The progress of aviation has made this necessary since the airman passes so quickly from one territory to another. Unless something is done, Africa of the future will be saddled with a multiplicity of scales, styles and projections. As no other nation is likely to adopt the British units of measurement, unless we change to the metric system, yet another complication will be added to the map difficulties of the airman.

Before the conference terminated, resolutions were passed recommending that a central pool of survey instruments should be formed from which Dominions and Colonies could borrow on certain terms; that the *Empire Survey Review* should be continued notwithstanding some loss, as a means of keeping up the standards of surveying technique; a resolution emphasizing the necessity for basing all categories of survey on a proper geodetic foundation; a resolution recording the opinion of the conference as to the value of its proceedings for the discussion and interchange of views on the improvement of survey technique. The conference also decided that it is desirable to hold triennial conferences lasting for two weeks.

H. L. C.

Electrical Interference with Broadcasting

THREE years ago the Institution of Electrical Engineers appointed a special committee to consider the trouble caused by the interference of various kinds of electrical devices with radio reception. This nuisance has been gradually getting worse owing to the growing sensitivity of modern receivers. The report has now been published (Inst. Elec. Eng., Savoy Place, W.C.2. 6*d*. post paid) and was commented upon in NATURE of August 1. The committee was fully representative of all sections of the industry on both the radio and engineering sides.

A method of measurement of interference has been agreed upon, and instruments have been developed capable of indicating with sufficient accuracy the amount of interference caused by much of the electrical apparatus which causes trouble. The technical position has been cleared up, and it is considered that no undue extra expense will be involved in the design and construction of apparatus that will bring the interference caused within an acceptable standard. The apparatus which is likely to cause the most interference is classified as follows: (1) lifts in buildings; (2) trolley-buses and trams; (3) household electrical appliances; (4) small electric motors; (5) 'neon' display signs; (6) certain rectifiers for power plant and (7) electro-medical apparatus. In an appendix to the report, a brief account is given of the researches undertaken in connexion with these seven groups.

In addition, although there is at present little interference with ordinary broadcast reception due to the ignition systems on motor-vehicles, it is probable that, unless corrected, it will interfere with the television reception of the future. There are other causes of radio interference such as electric signalling gear on railways, but at present they produce only minor effects. Real progress has been made in finding the most effective methods of correction in each of the seven groups given above. As a result of Post Office activity, a considerable amount of radio interference correction has been taking place during the last few years.

The first case where radio interference correction was in effect made compulsory was that of traffic signals. The Ministry of Transport now requires all traffic signals to be fitted with components which effectively prevent interference. This was achieved without much difficulty. The second case was that of trolley-buses, where much practical progress has been made. It is now clear that the various technical aspects of the problem are approaching solution, and it is necessary to consider whether compulsory powers should be conferred on some authority so that radio interference may be suppressed in those cases where it can only be done with the help of such an authority. The manufacturers of appliances and plant definitely support the view that there should be some recognized 'mark' which could be affixed to all portable apparatus as a guarantee that the apparatus complies with non-interference requirements. They consider that the sale of appliances which do not meet those requirements should be prohibited. It is essential that imported articles should be subject to the same regulations as home-produced articles and should bear the 'mark'. It is only through legislation that this question can be dealt with successfully. As a rule, it is not the man who buys and uses the apparatus, but his neighbour, who suffers from the resulting interference.

In view of the fact that it is generally cheaper to incorporate suppression devices in the original design of the equipment than to fit them after installation, it is recommended that compulsory powers should be conferred on some authority. It is anticipated that there will be only a small number of owners of interfering equipment who will refuse to apply remedial measures. It is recommended that the Electricity Commissioners should be the authority to issue regulations regarding both new and existing equipments and that the Post Office be charged with enforcing them. British Standards Specifications have already been issued giving the standard ratings for condensers, 'resistors', inductors and similar apparatus for incorporation in suppression devices. The specification for a standard interference-measuring instrument will cover the characteristics and performance requirements recommended by the Special International Committee on Radio Interference. It will include a detailed design for a portable instrument which will enable manufacturers to ascertain what values of components should be used to reduce interference within the prescribed limits.

In a statement made by Mr. C. C. Paterson, the chairman of the Committee, concerning the report, he points out that should the regulations be put into force, the normal procedure would be very much as at present. There would not be an army of inspectors searching out for trouble. Action would only be taken by the Post Office on receipt of a complaint of interference, and these complaints would become fewer in number as new apparatus bearing the 'mark' came into use.

Industrial Development in South Africa

THE Department of Commerce and Industry of the Government of the Union of South Africa has published a review of the material, scientific and educational progress made in connexion with the development of industry during the twenty-five years up to 1935*. Primarily, its purpose is to give an accurate picture of the conditions and prospects in what are described as the secondary industries, for agriculture and mining are otherwise dealt with and are only referred to in so far as they have a bearing on the other and less firmly established industries. The information it contains as to the conditions, facilities, costs, etc., in various districts and the progress of the numerous industries which have been established will also be found to supply a valuable scientific interpretation of the facts for the use of those who are or may become interested in the industrial future of the country.

In round numbers, the following figures give a picture of the expansion that has taken place in the twenty-five year period—employees have increased from 66,000 to 195,000, horse-power from 140,000 to 1,400,000, and total wages from 4 to 27 million pounds. The classes of industries dealt with and analysed statistically include fuel industries, iron and steel production, heavy chemicals and food production (sugar, wines and fisheries), together with other important developments which are taking place in connexion with the introduction of such manufactures as cement, pottery, clothing and textiles.

In these changes, the importance of research appears to be fully realized, and it is being fostered as an aid and guide in obtaining the best results. At Mount Edgcumbe, the sugar industry has, at a cost of £13,000, established an experimental station, which is run at an annual charge of about £9,000. On the agricultural side, its main function is the search for new canes of superior sugar content and of higher resistance to disease. There are also a chemical side, dealing with manufacturing methods and processes, and an engineering section to investigate mechanical problems.

The Union Government conducts research in connexion with the fisheries, investigating life-histories and the intensity of operations and engaging in technological research on canning, smoking and other processes. Marine biological work is carried on in the specially designed research ship *Africana*, which took over the duties in 1931, while shore investigations in this department are conducted at the Laboratory and Aquarium at St. James, near Cape Town.

In a country making rapid advances towards industrialism, and possessing rich stores of natural wealth, much special research is necessary in order to ascertain the best methods of making use of and adapting its resources to its own needs and that of export trade. Such work is being done on the coal supplies, the phosphates, the clays and other materials offering scope for increased usefulness. The use of gas, for example, might be greatly increased and developed.

The value of standardization has been recognized, and the editor takes the opportunity of impressing on his local readers its importance in eliminating ambiguous and misleading descriptions, in preparing dimensional standards and in specifying physical and chemical properties of materials, methods of testing, and safety codes. The South African Standards Institution, which is associated with the British Standards Institution, is conducted by a main committee representative of Government departments, technical societies and trade and industrial bodies, and there are five sectional committees dealing with mechanical, electrical and civil engineering, chemical and fuel matters respectively. In any work undertaken, the initiative lies with the interests concerned, and after tentative standards have been prepared they are submitted to the associated institutions, and those chosen are circulated for comment and recommendation. It is claimed that in this way the final standards approved should meet local conditions and requirements and then the industry or trade concerned may, if it desires, adopt them in its daily policy and practice.

It is to be noted also that a comprehensive scheme of training and technical education is now in being. The adoption, in 1922, of the Apprenticeship Act, marked the beginning of a new era in industrial legislation, and since then, 15,000 lads have completed their apprenticeships in accordance with its provisions and under the supervision of the committees of employers and employees which assist in its administration. The Act is operative in twelve groups of industries, and the general practice is a five-year training of young people after completing the primary and, in some cases, part of the secondary school course. They are then indentured to individual employers and are required to enrol for part-time courses at the technical colleges, a portion of their attendance there being timed to take place during ordinary working hours. For those resident in places far removed from centres where technical colleges exist, the Government has arranged for correspondence courses under the ægis of the Witwatersrand Technical College and, where students show satisfactory diligence, employers are responsible for the class or correspondence fees. It will thus be seen that South Africa is making every endeavour to provide for the needs of her technical students in the most practical way, and it may be premised that these preparations will react most favourably upon future industrial developments.

Science News a Century Ago

The Reef at Pernambuco

FROM Ascension, H.M.S. *Beagle* sailed for Bahia in order to complete the chronometrical measurement of the world. Arriving there on August 1, 1836, she sailed for the Cape Verde Islands on August 6, but being delayed by unfavourable winds on August 12 put in at Pernambuco, anchoring inside the reef. Of this reef, Darwin wrote: "I doubt whether in the whole world any other natural structure has so artificial an appearance. It runs for a length of several miles in an absolutely straight line, parallel to, and not far distant from, the shore. It varies in width from thirty to sixty yards, and its surface is level and smooth; it is composed of obscurely stratified hard sandstone. At high water the waves break over it; at low water its summit is left dry, and it might then be mistaken for a break-water erected by Cyclopean workmen. . . . Although night and day the waves of the open Atlantic, turbid with sediment, are driven against the steep outside edges of this wall of stone, yet the oldest pilots knew of no tradition of any change in its appearance. This durability is much the most curious fact in its history; it is due to a tough layer, a few inches thick, of calcareous matter, wholly formed by the successive growth and death of the small shells of Serpulæ, together with some few barnacles and nulliporæ. These nulliporæ, which are hard, very simply-organised sea-plants, play an analogous and important part in protecting the upper surfaces of coral-reefs, behind and within the breakers, where the true corals, during the outward growth of the mass, become killed by exposure to the sun and air. These insignificant organic beings, especially the Serpulæ, have done good service to the people of Pernambuco; for without their protective aid the bar of sandstone would inevitably have been long ago worn away, and without the bar, there would have been no harbour". Darwin in 1841 described the bar in detail in the *London and Edinburgh Philosophical Magazine*.

Monument to Champollion

ON August 13, 1836, the *Athenæum* said: "The monument erected at Figeac to the memory of Champollion, is an Egyptian obelisk of the purest and severest style, of very hard granite from a quarry near Figeac. It bears an inscription to the following effect: 'To the memory of F. J. T. Champollion, who first penetrated into the mysteries contained in the writing and monuments of ancient Egypt, and who was taken from Science by a premature death on the 4th of March 1832. He was born at Figeac the 23rd of September 1791'." Champollion died in Paris, and was buried in the Père-Lachaise cemetery. His grave is marked by an obelisk bearing a medallion.

Aerial Surveying from Balloons

IN the *Mechanics' Magazine* of August 13, 1836, is a note from the *Scotsman* referring to the work of Charles Green (1785–1870), the aeronaut who up to that time had made 218 ascents. On the last occasion when Lord Clanricarde went up with him, he observed, it was said, that surveyors and architects could with greater facility take plans of noblemen's estates by ascending in a balloon, as they could have a bird's-eye view of every locality, and if they only once adopted that method they would never relinquish it. Since the suggestion was made, an artist named Burton had called on Mr. Green to obtain the plan of a balloon constructed so as to be used for this purpose. The inventor proposed to fasten the car to the balloon by a swivel and to build a waggon to which the balloon could be attached. The waggon could be conveyed to any place a surveyor required, where, on a calm day, he could take plans, carrying with him the proper instruments.

Sir Charles Bell leaves London

SIR CHARLES BELL, the eminent surgeon, having accepted the chair of surgery at Edinburgh left London in August, 1836. One of the last letters he wrote from his residence, 30 Brook Street, was to his sister Miss Bell. In this he said: "The house is in a hustle. Books gone—pictures packing. People surveying the house! This does look like a change. All my sacred corners usurped—a naked house not a home. . . . I leave no enemy behind me, and Marion is universally beloved. . . ."

"While the season lasts, our society is all we could wish; but now our friends hurry to their better houses in the country, where they invite us, but where we cannot go. Many a long day we have been left solitary in a crowd, losing spirits and health."

"Without independent fortune, the relations which we have formed with society are not without their drawbacks. I must be independent and through exertion more than fortune. I must pursue that course through which I have attained station to feel comfortable. I could have made a fortune, and so my friends say, but I could not also attain to what I am, and to what they would have me. . . ."

Statistical Desiderata

IN the Section of Statistics at the sixth meeting of the British Association held at Bristol in August 1836, Mr. W. R. Greg brought forward proofs of the total deficiency of statistical information in some subjects of international importance, and the unsatisfactory nature of that which had been collected by public authority in others. From examination of population tables, tables of births and deaths, criminal statistics, the statistics of education, of illegitimate birth and of stolen property, the author was led to conclude, that "with the exception of the revenue and commercial tables, no general documents yet exist in England from which any philosophical influences can be safely drawn, and that till the materials are wholly re-collected, all attempts to elicit such inferences can only end in disappointment and error". In order to obtain more satisfactory results in future, he deems it highly necessary to depart from the plan so commonly resorted to, of issuing circular queries, and to commit the task of obtaining authentic and complete information to individuals who shall make the execution of it their professional duty and whose labours shall be remunerated accordingly.

County Natural History Societies

IN a paper entitled "A Proposal to Establish County Natural History Societies for Ascertaining the Circumstances in all Localities which are

Productive of Diseases or Conducive to Health", Dr. J. Conolly, late professor of the practice of medicine in the University of London, after pointing out the advantages which the country practitioner possessed over those living in towns, especially as regards the intimate acquaintance he gradually acquired concerning every circumstance in the locality, suggested the formation in every county in England of a society consisting of scientific men of every class and description and comprising the following sections: (*a*) statistics, (*b*) geology and mineralogy, (*c*) geography, (*d*) meteorology, (*e*) agriculture, (*f*) botany, (*g*) archæology, (*h*) chemistry and (*i*) medical topography and statistics. The business of this last section would be "to apply all the exact knowledge furnished by the other sections to the subject of health and disease; to note, with extreme care, the relation of phenomena developed in the human body to the natural or statistical or historical and political and moral circumstances in which the subjects of such phenomena were placed". (*Trans. Prov. Med. and Surg. Assoc.*, 1, 180; 1836.)

Societies and Academies

Paris

Academy of Sciences, June 29 (*C.R.*, 202, 2109–2220).

Jean Tilho: The present condition of the zone of capture of the Logone by the Bénoué. Further measurements and observations confirming the possible danger of the capture of the Logone (Tchad basin) by the Bénoué (Niger basin).

Vito Volterra: The integration of the equations of biological fluctuations.

Claude Chabauty: Certain ternary diophantic equations.

Farid Boulad Bey: The general forms of equations of nomographic order 6 and 5 representable by conical nomograms.

S. Bucheguennce: The deformation of Bianchi surfaces.

Georges Giraud: A general class of equations with principal integrals.

Alexandre Ghika: The interpolation of analytical functions.

Emile Merlin: The nature of the trajectories of certain perfect heterogeneous fluids.

Henri Mineur: The galactic rotation of globular clusters.

Jean Jacques Trillat and Mlle. Renée Vaillé: A method of measuring the adsorption of oils by metallic surfaces.

Pierre Cibié: A method of laboratory control of the light projectors of motor-cars.

A. Hautot: The K-radiation of crystallized boron. It is concluded that the remarkable variation of the electrical conductivity of boron with temperature is due to a variation of the energy distribution of the conductivity electrons.

Jacques Errera Pol Mollet and Mary L. Sherrill: The infra-red absorptions of liquid hydrocarbons. The influence of the double linkage.

Henri Bizette and Belling Tsaï: The thermal variation of the magnetic double refraction of nitric oxide (NO) and of compressed oxygen.

Mlle. Madeleine Gex: Variations in the ultra-violet spectrum of phenol as a function of the *p*H. Over a range of *p*H from 1 to 12, the changes in the ultra-violet spectrum suggest four changes in the structure of the phenol molecule.

F. Hammel: The analogy of the monohydrated sulphates of the magnesium series. Results of X-ray studies of the monohydrated sulphates of magnesium, manganese, iron, cobalt, nickel, copper and zinc.

François Bourion and Mlle. Odile Hun: The cryoscopic determination of the total hydration of the ions of hydrochloric acid.

Mlle. Cécile Stora: The mechanism of the Becquerel effect of organic molecules.

Tr. Négresco and W. J. Crook: The equilibrium relations of the oxides of iron in the slag of refinery furnaces.

Mlle. Jeanne Boulanger: The systems zirconyl oxalate, alkaline oxalates and water.

Pierre Carré and Louis Peigné: The relative mobilities of the normal alkyl radicals in their chlorothioformates.

Henri Wahl: The chlorination of *p*-chlortoluene. The chlorination of *p*-chlortoluene gives a mixture containing 58 per cent of the 2,4.dichlortoluene and 42 per cent of the 3,4.compound. This proportion is not affected by the nature of the catalyst, or by variations of temperature between 20° and 40° C.

Pierre Legoux: The origin of the gold of the Guinea-Sudan borders.

Louis Dongieux, Louis Dubertret and Henri Vautrin: The Oligocene and Burdigalian of the Syrian desert.

Maurice Parat: The Oxfordian and Kimmeridgean of Milne Land (Eastern Greenland).

André Aurio: The suitability of a cycle of 334 years for meteorological predictions.

Henri Colin and Marcel Simon: The proportion of ash and its alkalinity in the beetroot.

Etienne Foex and Maurice Lansade: A bacteriosis of the banana tree.

M. and Mme. Fernand Moreau: The toxicity of some cations for the Saprolegnieæ.

Léo Espil and Gabriel Mandillon: The action of bromacetates on various alkaloids. Sodium bromacetate reacts with strychnine sulphate, giving a non-toxic product. The toxicity of this alkaloid would appear to be connected with the existence of a free amino group.

Mme. Véra Dantchakoff: Sex hormones and the role of the placenta in the ontogenesis of mammals.

Israel and Michel Magat: The ultra-violet spectrum of normal and leucæmic blood.

Fred Vlès: The conditions of stimulation of fluorescence of proteins.

Ernest Kahane and Mlle. Jeanne Lévy: The origin of the choline of sperm. The existence in sperm of free choline is a secondary phenomenon due to the action of a diastase on a precursor of choline.

Ali Mustapha: The action of the cholera vibrion on milk and cholerigen power.

Georges Blanc and Marcel Baltazard: The influence of privation on the development of the virus of murin typhus in the flea (*Xenopsylla Cheopsis*)

Alexandre Besredka and Michel Bardach: The intra-cutaneous immunization of rabbits against epithelioma inoculated in the eye. Intra-cutaneous epithelioma, a benign tumour, acts as a true vaccine against epithelioma of the eye, a malignant tumour.

Amsterdam

Royal Academy (*Proc.*, 39, No. 6, June 1936).

W. H. KEESOM and G. SCHMIDT : Researches on heat conduction by rarified gases. (1) The thermal accommodation coefficient of helium, hydrogen, neon and nitrogen on glass at 0° C.

J. BOESEKEN : The oxidation products of thiourea. The dioxide as derivative of sulphoxylic acid (H_2SO_2).

E. D. WIERSMA : Physical resemblance in connexion with mental similarity (1). Researches on the inheritance of temperament and resemblance of offspring and parents.

K. MAHLER : An analogue to a theorem of Schneider (2).

H. FREUDENTHAL : (1) A class of rings in Hilbertian space. (2) The abstraction of the concept of an integral.

W. BLEEKER : Meteorological data from the three Dutch expeditions to the Karakorum (1). Observations of pressure, temperature, humidity, etc., at various stations in the Karakorum range.

T. WEEVERS : A consideration of some phytochemical problems. The phytochemical characteristic of a species, genus or family of plants is not a single compound, but a particular combination of several compounds.

T. E. DE JONGE-COHEN : Radix præmolarica unilateralis.

N. SUZUKI : The diencephalic and some other systems in *Xantharpyia amplexicaudata* (1).

B. VAN DER EYKEN : Dentition and teeth development in the irisforelle (*Salmo irideus*) (6). Teeth development.

A. CHARLOTTE RUYS : The isolation of typhoid bacilli from water. Wilson and Blair's medium readily permits of the isolation of the typhoid bacilli from infected water.

D. VAN DANTZIG : Ricci calculus and functional analysis.

Geneva

Society of Physics and Natural History, May 7.

KURT H. MEYER and W. LOTMAR : Note on the elementary lattice of crystallized caoutchouc. From a study of the interferences, the dimensions of the elementary lattice of crystallized caoutchouc can be calculated. It is monoclinic ($a = 8\cdot54$ A.; $b = 8\cdot20$ A.; $c = 12\cdot65$ A.; $\beta = 83°$). The arrangement of the atoms in this lattice, which includes eight isoprene radicals, can be established. Thus, caoutchouc should be classed in the C^{5}_{2h} spatial group.

A. WEINSTEIN : The equations of vibration of a plate. Calculation of close upper and lower limits for the frequency of the overtone of a square clamped plate.

ERNEST C. G. STUECKELBERG : Continuous γ-radioactivity and unitary field theory. The Fermi explanation of continuous $\beta+$ radioactivity allows for a recombination between the created positive electron and an orbital electron. The annihilation radiation can escape from the atomic system even if there is not enough energy available to produce a positive electron. Thus there is a pure and continuous γ-ray emission. Considering electron, neutrino, proton and neutron as different quantum states of one elementary particle, only four different transitions are possible if conservation of charge and Dirac's equation are postulated. They explain the Fermi formula of β-decay and the nuclear exchange forces of Heisenberg and Majorana. If a neutrino theory of light is developed, the electric field and the material field (particles) can be described by the 16 components of a unitary spinor field (see also NATURE, June 20, p. 1032, and June 27, p. 1070).

B. SUSZ and S. FRIED : The Raman spectrum of gallic acid, of some of its derivatives and of tannin. The authors give the Raman spectrum of gallic acid, of methyl gallate, methyl trimethylgallate, triacetylgallic acid and Chinese gallotannin with some interpretations of the frequencies found.

Moscow

Academy of Sciences (*C.R.*, 1, No. 7, 1936).

S. SOBOLEV : Evaluations concerning the families of functions having derivatives with integrable squares.

L. KANTOROVICH : The general theory of operations in semi-ordinated spaces.

A. I. ALICHANIAN, A. I. ALICHANOV and L. A. ARZIMOVICH : The law of the retention of impulses at the annihilation of positrons.

V. ARKADIEV and A. MOROSOVA : Photographic representation of a Hertzian dipole.

N. SELJAKOV : To what class of symmetry does ordinary ice belong ? There are two modifications of ice ; α-ice is hexagonal and β-ice is rhombohedral.

M. ELIASHEVICH : The rotation-vibration wave equation for a polyatomic molecule.

D. RAUZER-CHERNOUSOVA : The Fusulinidae and the stratigraphic subdivision of the oil-bearing limestones in the Sterlitamak district.

J. M. URANOVSKIJ : The role of the nervous system in the regeneration of the extremities in axolotl.

Sydney

Royal Society of New South Wales, June 3.

A. H. VOISEY : The Upper Palæozoic rocks around Yessabah near Kempsey, N.S.W. The various rock types in an area of about thirty square miles are described, classified and mapped, these rocks being mainly of sedimentary origin. This work reveals a very interesting story of bygone ages. More than three hundred million years ago there existed a shallow sea abounding in life ; but many organisms were killed by showers of ash from violently explosive volcanoes. Later came uplift, and then another subsidence again ushered in marine conditions. The climate then was cold, and icebergs floated about on this sea fringed with active volcanoes. Further uplift and depression followed, with a gradual dying out of volcanic activity. After a final uplift, came extraordinary changes—pressure folded the rocks into great arches and troughs, and huge rock masses were displaced along cracks. Then for perhaps two hundred million years the land surface was gradually but effectively worn down, until it was but little above sea-level : uplift followed, and out of the highlands so formed the present Macleay River cut its valley.

GERMAINE A. JOPLIN : The Ben Bullen Plutonic Complex, N.S.W. The Ben Bullen complex consists of two intrusions of partial magma. The earlier mass is of noritic composition, and has differentiated *in situ*. The later intrusion is a quartz-mica-diorite, and this has reacted with the solid norites and given rise to a series of cognate hybrids. Five chemical analyses show that the complex is closely related to the Hartley series, and possibly represents a northerly extension of the Hartley-Bathurst bathylith.

H. G. RAGGATT: Geology of the north-west basin of Western Australia, with particular reference to the stratigraphy of the Permo-Carboniferous. The stratigraphy and lithology of the Permo-Carboniferous system in the north-west basin of Western Australia are described in detail, and a subdivision into series and stages suggested. Correlation of these rocks with the Permo-Carboniferous of the Irwin River is discussed. An outline of the stratigraphy of the Cretaceous and the geological history and structure of the region are given.

WINIFRED MANKIN: An attempt at quantitative analysis of silver-gold alloys. Arc spectra were obtained from alloys of silver and gold in various proportions in the attempt to find a definite relation between the ratio of the intensities of corresponding lines in the spectra of the two metals and their proportions in the alloy. The alloy formed a bead in the crater of a carbon arc. Three pairs of corresponding lines were examined. No regular relations were obtained, and this is due mainly to the relative rates of volatilization varying considerably with slight changes in the arc conditions. Chemical analysis showed that the relative proportions of the metals were changed considerably, and in an erratic manner, by the passage of the arc. Suggestions are made for modifications of method.

H. FINNEMORE and JOYCE M. COOPER: Cyanogenetic glucosides in Australian plants (4). *Zieria lævigata.* The leaves of this rutaceous plant yield by the action of its own enzyme 0·2 per cent of hydrocyanic acid, and approximately twice this amount with additional enzyme. It is shown that this is due to the decomposition of zierin, the glucoside of meta-hydroxybenzaldehyde cyanhydrin.

Science and Armaments

NOTHING could demonstrate more completely what the Prime Minister recently termed the madness of re-armament than the fact that in the recent debate on defence in the House of Commons, Government spokesmen failed to reply to the two questions which are uppermost in everyone's mind: What is the limit of the expenditure involved, and against whom is the programme directed? The questions indeed cannot be answered. There is no limit; and to express one's fears in definite words might well be to start the conflagration universally dreaded. Unless intelligence once again takes control over passion and prejudice in the relations of nations, and force is relegated to its proper function of maintaining law and order, there can be no escape from a conflict which would involve ruin for all. Nor can we hope for peace among nations any more than among individuals if we encourage the view that wrongs cannot or will not be dealt with by reason or persuasion and can only be redressed by force.

Even the staunchest supporter of the present programme of re-armament and defence in Great Britain can scarcely avoid misgivings as to its eventual outcome. Unless at the same time we can ensure that some real attempt is made to eliminate the root causes of international friction and misunderstandings, to control the mischief wrought by economic nationalism, and to secure a settlement of difficult economic and racial questions on a basis of social justice and not of *force majeure*, the attempts to strengthen armaments, however sincerely aimed at national defence, can only bring conflict nearer. Collective security is in fact the only possible form of security to-day. All else is merely a matter of relative insecurity and how soon the crash will be.

The most serious feature of the recent debate was, however, the absence of reference to the imperfection of defence against modern methods of warfare. Responsible technical and scientific opinion is at one in agreeing that any protective measures for the general population against air attack by chemical means is at best imperfect and inadequate, and scientific workers cannot evade their responsibility for warning the population of the limitations of the measures now being considered by the Air Raid Precautions Department of the Home Office. There could be no greater calamity than for the population to be deluded into believing itself to be largely immune from the consequences of such attacks in the event of an outbreak of war. The proposals to transfer part of Woolwich Arsenal to western and northern districts of the country, and to duplicate the coal oil plant at Billingham in South Wales instead of on the same spot, indicate in themselves that the effective defence even of munition centres is problematic.

To this extent, therefore, scientific workers will be in general sympathy with a resolution which was submitted at the meeting of the British Medical Association at Oxford in July. The resolution, however, proceeded further, and recommended the Association to take the initiative with the object of securing the co-operation of the medical profession of all countries to prohibit the manufacture of poison gas. Scientific workers would undoubtedly join in condemning the use of poison gas in conjunction with other forms of warfare as inhuman and degrading to civilization, even though they may doubt whether it is worth while to endorse too hastily proposals to discriminate against one particular kind of warfare.

The impossibility of effective defence measures against chemical warfare for the civil population should not blind us to the difficulty of securing its prohibition if resort was once made to warfare. Events in Abyssinia have demonstrated afresh the impossibility of relying on the pledges to a particular form of warfare when once a nation has broken its general pledge, even under conditions when provocation or retaliation in kind are impossible. Despite this impracticability, which was emphasized by speakers in the discussion at the British Medical Association, an amended resolution was passed which, condemning gas warfare, called on the Council to do everything in its power to secure the co-operation of the medical profession in all countries to prohibit the use of poison gas.

Apart from the serious doubts entertained by authorities as to the practicability of chemical warfare being prohibited, it is even open to doubt whether the restriction of particular methods of warfare is desirable. The very ruthlessness with which war is prosecuted with modern weapons, and the cynical disregard of international obligations or of any standard of humanity or chivalry in the conduct of a campaign, may even prove a gain to mankind in the end if the lesson is learnt that the real problem is that of eliminating and not merely of mitigating warfare. As Sir Henry Thuillier, who during the Great War was Controller of Chemical Warfare, has suggested, the interests of humanity might be better served if the whole populace appreciated in advance that the direct effects of resort to warfare would not be confined to the combatant services.

The lecture to which we refer has now been published in the *Journal of the Royal United Services Institution* for May last, and it will well repay study by all those who are really concerned with constructive efforts to establish peace and co-operation, and to secure the surrender or abatement of these national claims or rights which most hinder the working of a system of collective security and constitute the gravest danger to peace. Sir Henry Thuillier does much to stimulate clear thinking on questions where side issues have so long diverted attention which should have been given to the major question of eliminating the use of war altogether.

Proposals to restrict methods of warfare have arisen from economic considerations, as in regard to the battleship, but much more commonly on humanitarian grounds. In regard to the latter, a clear answer has rarely been given to the fundamental questions: Will the proposed restriction actually reduce the inhumanity of war, and will the agreement be effective? The voluminous discussions which have taken place on chemical warfare, the submarine, the use of tanks, have not led to any general agreement on the answers which should be given. On the contrary, there is abundant evidence of the muddled thinking which Sir Henry Thuillier warns us is a most serious danger to peace and security.

Certain questions have to be frankly faced in any discussion on restrictions if clear thinking is to be ensured. Since all war is indescribably inhumane, is it to the benefit of the human race to try to reduce its inhumanity in two or three minor directions only? Nothing can really lessen its horrors, and it may well be better that the peoples should realize this in order that they may make every effort to put an end to it altogether. If it were known in advance that the effects of warfare would fall as ruthlessly on all classes of civilians, whether on the statesmen who had bungled diplomacy, or financiers or manufacturers or others whose desire for trade expansion or profits had contributed to its outbreak, as on members of the fighting services, much more serious and constructive efforts to prevent it might be made. On the question whether the proposed restrictions could really reduce the inhumanity at all, not only is there need for a close sifting of opinion but also for a frank facing of facts. The desire to abolish submarines or poison gas is largely based on lack of knowledge, false sentimentality, conservatism, fear of unknown methods and perhaps especially the fear that our adversary may prove more efficient in these new methods than ourselves. To the third question, whether we could have a reasonable guarantee that agreements of this sort would not be evaded, or even openly repudiated under stress of defeat, events in Abyssinia suggest a very definite and depressing answer. The only hope seems to be to organize a society in which constructive effort will be used to eliminate war altogether and to make civilized peoples realize the horrors and inhumanity of any such conflict between nations.

It is well that scientific workers should, as was done in the recent discussion at the meeting of the British Medical Association, dissociate themselves from the prostitution of scientific results in warfare or for other nefarious purposes: it is equally their duty, however, to do all in their power to ensure clear thinking on such matters. The pertinent remarks of Sir Henry Thuillier about the alleged inhumanity of gas warfare, or even of the use of the submarine, should be welcomed by all scientific workers, and they reveal the essential childishness of much of the discussion on this point.

All war is inhumane ; and to fritter away effort discussing the relative inhumanity of different kinds of warfare is rapidly becoming intolerable. What has to be recognized is that war is not only inhumane but also under modern conditions its renunciation as an instrument of national policy, and as a means of dealing with international disputes, is absolutely essential if civilization is to survive. The question really is whether there is yet time to carry out the constructive work involved both in developing adequate machinery for settling international disputes, and for removing the causes of international friction and misunderstanding, before the world is overwhelmed in another outbreak. Scientific workers owe it to themselves, no less than to their science and to their civic responsibilities, to strain every effort to ensure constructive thinking in these matters and to promote the formulation and execution of policies adequate to secure that the enormous powers now at our disposal are used for the advantage of mankind instead of its destruction.

A Sketch of World History

World History : the Growth of Western Civilization. By R. Flenley and W. N. Weech. Pp. xix + 757. (London : J. M. Dent and Sons, Ltd., 1936.) 12*s*. 6*d*. net.

WORKS on general history have often been noticed in NATURE, especially from the point of view of the space and the position which they assign to science. There has undoubtedly been a marked improvement in the matter, and the very attractive book under notice is a good example, suggesting also one or two points of criticism in its presentation. It is certainly the best thing of the sort that we have seen in English—a sketch of world history in some seven hundred pages with abundant illustrations and excellent maps and diagrams and written throughout by both authors with full knowledge and an almost perfect impartiality.

The questions of how to present the vast mass of material, and for whom one is writing, are, in this kind of book, supremely difficult. In this one, the readers who will gain most from it are those who have a fairly good knowledge beforehand and are glad to have it revived in a well-ordered summary up to date. For students who are approaching the subject for the first time, the language, ideas and implications of the writers are probably too difficult. This is the case more especially with Mr. Flenley, who does the modern portion. One often feels that the essential points could be conveyed without such an array of long and abstract words and in shorter sentences. On the other hand, Mr. Flenley grapples valiantly with the problem of including all sides of history—music, art and literature as well as science—and his allowance for science is relatively generous. Yet even so, how can one excuse in such a survey the complete omission of the marvels discovered in the heavens and presented so clearly in the Astronomer Royal's recent "Worlds Without End" ?

Mr. Weech, who is an old schoolmaster, has a crisper and simpler style. Some of his short sayings are admirable ; for example, "It was the spoken word, not the written, that counted with the Greek and made him the teacher of the western world. . . . He was an excitable, quarrelsome, kind-hearted creature. He was continually fighting his neighbour in the next valley, but when he had finished, he did not, like other conquerors, mutilate, crucify or scalp his captives, nor did he convert them into gladiators." On the other hand, Mr. Weech is much less adequate in his account of ancient science. The wonderful discoveries which have recently been made of the mathematics of Babylonia, and the medicine of ancient Egypt, find no place. The institution of the calendar is naturally mentioned, but not its connexion with the heliacal rising of Sirius. More should have been given of the sort of matter which Prof. Gordon Childe has just put out in his "Man Makes Himself"—the origins of civilization—even if further cuts had to be made in the political sections. It is also doubtful in the later portion whether the Impressionist and Post-Impressionist painters deserve the several pages which they get.

There is room, however, for wide difference of opinion as to such relative values, and the book is strongly to be commended in the sense mentioned above. The sober hopefulness of the "Conclusion" —after a summary of the successes and failures of the League of Nations—hits the mark very well.

F. S. MARVIN.

Classical Dynamics

Theoretical Mechanics:
Dynamics of Rigid Bodies. By Prof. William Duncan MacMillan. Pp. xiii + 478. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 36*s*.

WITH the publication of this volume on rigid dynamics, Prof. MacMillan has completed a task of first-rate importance. This work, together with its companion volumes on statics and particle dynamics and on the theory of the potential, constitute a trilogy which, for a long time to come, will be welcomed by successive generations of honours students of physics and of engineering. Despite the fact that the centre of interest has in some measure shifted from such studies, there was a real lack of a treatise which should serve the needs of this generation as Routh served those of an elder line of students. Routh's works, and Thomson and Tait, have become classics, and as is the fate of most classics are rather read about than read. No more brilliant introductions to the advanced study of mechanics are to be found than those of Horace Lamb. It is rare indeed to find a first-rate intellect which combines an almost unexampled power of exposition with a sympathetic appreciation of the needs of the average student and a capacity for keeping mathematics in touch with physical reality. Lamb had these gifts in full measure, and his treatises on mechanics are an invaluable expression of these gifts.

But a work was needed which should carry the story farther and should view the subject from a rather different angle, and Prof. MacMillan's book fulfils this want. His treatment is severely classical; "the three laws of motion as given by Newton furnish the foundation for the entire structure"; and the section 'E' of the author index contains but the names of Eisenhart and of Euler. Both the geometrical and the purely analytical methods of attack are developed, and the author's preliminary account of the algebra of vectors is a model of clarity and of compression.

A chapter on moments of inertia follows, and here, perhaps, a digression on a point of very elementary, and yet of very general interest, may be permitted. The author defines the moment of inertia of a system of particles *with respect to a plane, line or point* as the "sum of the products of the mass of the particle into the square of the perpendicular distance of the particle from the plane, line, or point (or merely the square of the distance in the case of a point)". In doing so he has followed the example of Routh and of other classics. But many authors and teachers seem to be obsessed by the notion that the term *moment of inertia* has no meaning apart from an *axis*. Hence they lose the chance of developing that most instructive method of calculating the moment of inertia of a sphere about a diameter, which consists in calculating it *about the centre* by the simplest of all integrations—that of $4\pi r^2\rho.dr.r^2$ through the volume of the sphere, hence leading to $\frac{3}{5}Ma^2$ as the required value. The moment of inertia (I) about a diameter follows at once from the consideration that I_x is equal to $\Sigma m(y^2 + z^2)$ with two similar (and equal) expressions for I_y and I_z. Hence, by addition, we arrive at the value $\frac{2}{5}Ma^2$ with no more equipment than is required for the integration of $x^n.dx$ and for a knowledge of the geometry of a common brick. This simple method is obviously the one to be followed in elementary teaching. Which of the heroes who lived before Agamemnon invented it, the reviewer knows not, and would like to know; Binet (*teste* Routh) introduced the notion of moment of inertia with respect to a *plane* so far back as 1813.

The chapter on moments of inertia is followed by a series of chapters which deal with systems of free particles, general theorems on the motion of a rigid body, motion parallel to a fixed plane, the motion of a rigid body in space, integrable cases of motion about a fixed point, rolling motion and impulsive forces. This portion of the volume extends to some three hundred pages.

The hundred and seventy pages that remain are devoted to three important chapters, the first of which deals with Lagrangian equations, their application to holonomic systems and their extension to non-holonomic systems. The chapter closes with a brief account of Appell's equations, which are applicable equally to holonomic or to non-holonomic systems.

The penultimate chapter deals with the canonical equations of Hamilton, and the work closes with a discussion of the method of periodic solutions. Here, as in the more elementary parts of the book, the author extends a helping hand to the student by giving him a very clear résumé of the amount of matrix theory necessary for the comprehension of the argument. This chapter, one of the most interesting in the volume, deals with a method of attack which is both long and difficult, but which, as was remarked by its originator,

H. Poincaré, "is the only worth-while method that is known for a wide class of problems".

The book is by no means an easy one to read, but the difficulties which the reader will encounter are inherent in the subject. The author has the teacher's instincts, and has made the going as smooth as may be. Further, he has provided a large number of illustrative examples, of all degrees of difficulty, on which the student may try his hand.

If a word of general criticism be permitted, it is that the book would be considerably improved if its subject matter were more fully illustrated by examples taken from physical and engineering practice. True, the billiard ball, the top and the pendulum play a large part in the illustrations in the text, but the practical side of pendulum work is drawn from Routh, and in this, as in many other instances, examples are better studied in the light of modern practical work of precision.

The book fills a gap in the literature and may be heartily commended. A. F.

Mineral Resources of the French Colonies

Les ressources minérales de la France d'outre-mer

Publications du Bureau d'Études géologiques et Minières coloniales. 3 : Le zinc, le plomb, l'argent, le cuivre, l'or, les minerais radioactifs, le mica, les pierres précieuses, substances diverses. Pp. ii+394+5 plates. 40 francs. 4 : Le phosphate. Pp. ii+207+3 plates. 20 francs. (Paris : Société d'Éditions Géographiques, Maritimes et Coloniales, 1935.)

THE issue of these two volumes on French colonial mineral resources by the Bureau d'Études Géologique et Minières Coloniales will be welcomed by readers who have already made themselves acquainted with vol. 1 on coal and vol. 2 on iron ore.

Vol. 3 covers a number of important metals and minerals, including zinc, lead and silver by F. Blondel, copper by P. Lion, gold by P. Delaître, radioactive minerals by H. Buttgenbach, mica by P. Chomette, precious stones by A. Lacroix, and various other metals and minerals, namely, aluminium, asbestos, antimony, arsenic, barytes, diatomite, mercury, nitrate, platinum, pyrite, rock-salt, potash and mineral waters, by F. Blondel.

As the lead-zinc ore deposits of French North Africa may be regarded as forming a Mediterranean circuit with those of Spain and Italy, M. Blondel includes all three in a useful account of the lead-zinc ore deposits of the western Mediterranean generally. On the whole, this region is one of much importance from the point of view of the supply of these base metals. M. Blondel concludes this section by a statistical account in which he examines the national position in France as regards supplies of lead and zinc.

The importance of copper in modern industry, the large necessary imports and very small production in France, makes M. Lion's account of the French position as regards copper one of much interest. Of considerable interest also is his description of the geology of the copper deposits of the Niara basin to the west of Brazzaville in French Equatorial Africa, and his account of the economics of copper from the historical point of view as well as with regard to the present position.

In the section on gold, M. Delaître gives an account of the geology and distribution of gold in the French colonies, and explains the simpler methods of exploitation applicable by prospectors in opening up superficial deposits in newly-discovered gold areas. In a brief section on radioactive minerals, M. Buttgenbach mentions deposits other than those of the French colonies, and gives a very useful description of the important deposit of uraninite (pitchblende) and its alteration products at Chinkolobwe in the Belgian Congo. In the section on mica, M. Chomette deals with mica generally, but briefly, and refers particularly to Madagascar deposits of muscovite and phlogopite, of which the latter are the more important. Madagascar produces phlogopite of superior quality and appears to have large reserves.

The section on French colonial occurrences of gemstones by M. Lacroix makes an attractive feature, chiefly on account of the remarkable assortment of beryl, tourmaline and other minerals of gem quality in Madagascar pegmatites, which are especially interesting from the mineralogical and petrological points of view. It is interesting to read in this section of the doubts that were entertained up to about a century ago as to whether diamonds really existed in Africa. Since then, Africa, especially South Africa, has produced nearly all the world's diamonds; but it is a very curious fact that, although important discoveries of exploitable diamond deposits have been made in recent years in the Belgian Congo, Angola, South-West Africa Territory, Tanganyika, Gold Coast and Sierra Leone, no find of any importance has hitherto been recorded in French Africa. No diamonds have been found in Madagascar, and the occurrences in French Equatorial Africa are as yet of no economic importance.

In the closing section of vol. 3, M. Blondel states that the auriferous stibnite mine at Lucette in Mayenne, France, became exhausted and was closed in 1934, a reminder to us, if one be needed, of the wasting nature of the earth's mineral assets.

In vol. 4, which is devoted entirely to phosphate, the important deposits of phosphate in Morocco are accounted for by A. Beaugé, who deals with their geology and explains the working of the organization of the Office Chérifien des Phosphates; and E. Lenhardt, who deals with methods of exploitation and transport.

A separate section is devoted to Algeria and Tunis by P. Reufflet, and another to the marketing of phosphates by H. de Bailliencourt-Courcol. In another section, A. Lacroix deals with phosphatized land-surface deposits such as those due to the replacement of limestones by the action of solutions arising from leached coverings of guano, and corresponding aluminium phosphates formed by the action of similar solutions on trachytes and other igneous rocks.

Not the least interesting section of this volume from a scientific point of view is the one given to a discussion of the origin of sedimentary phosphate beds of marine origin by L. Cayeux. These beds have been formed at intervals from the earliest geological times, and on account of their importance as a source of phosphate fertilizers may be regarded as among the front-rank mineral resources from the point of view of human welfare. The problem of their origin is a puzzling one. M. Cayeux has long held the view that the formation of marine phosphate beds could only take place after a disturbance of the equilibrium of the sea floor. To this *sine qua non* of sea-floor disturbance, he now adds bacterial action as essential. In some way or other, which is not clear, the bacteria are roused from a state of dormancy to one of action by the disturbance of the sea floor, and set about elaborating phosphoric acid from the sea water, while phosphoric acid attacks any calcium carbonate that may be available, forming calcium phosphate. In this environment, he tells us, fish may flourish abundantly, and the accumulation of their remains is added to that of the phosphate deposited on the sea floor; but the extent to which they contribute is very variable. To the question "Are phosphate beds now forming on the sea-floor?" M. Cayeux replies very emphatically in the negative, and claims that the conditions essential for their formation do not exist at the present day.

Both volumes are well illustrated and indexed, are provided with useful bibliographies, and are likely to be serviceable for many years as works of reference on French colonial resources of the minerals with which they deal.

Formulæ of Medieval Painters

The Materials of Medieval Painting
By Daniel V. Thompson. Pp. 239. (London: George Allen and Unwin, Ltd., 1936.) 7*s*. 6*d*. net.

MR. DANIEL THOMPSON has been engaged for many years in the study of the large number of medieval MSS. containing recipes for carriers, grounds, pigments and mediums which are to be found in the libraries, both in Great Britain and elsewhere in Europe. The actual number of MSS. examined amounts to 157, and in this simply written book we have the outcome of a laborious research, involving problems in translation, and the testing out of many recipes in the laboratory and the studio.

Mr. Thompson has already given us the most perfect text of Cennino Cennini's book on painting and an excellent translation, a book on tempera painting which was the result of many years practice based on Cennino Cennini, and many other contributions to the literature of the subject, and this is his latest contribution. Those who wish to look further into the subject will find in *Speculum* of October, 1935, references to actual MSS. and recipes.

A German scholar would have doubtless written many fat volumes on the material collected by Mr. Thompson, and it is to be hoped that he will still undertake this work. In the meantime, this book, based on a course of lectures given in the Courtauld Institute, enables the connoisseur, artist and collector to obtain the distilled essence of his researches in an easily read and simple form. The classical work on the subject is "The Ancient Practice of Painting" by Mrs. Merrifield, and since then excellent editions of special MSS. have been made. Ernest Berger published certain MSS. in his learned volumes on the history of painting, and we have from Wilhelm Theobald an excellent edition of Theophilus, and there are others.

Valuable as these publications are, they have two defects. Many valuable recipes may be missed, and too much importance may be given to a single recipe. By making a critical examination and comparison of a large number of MSS. which have so far been neglected, not only are new recipes discovered, but so wide a survey also results in a more trustworthy judgment of what was the actual practice.

It is perhaps unnecessary to say that a book like this starts as many questions as it answers. The paragraphs dealing with verdigris alone, for the preparation of which many recipes exist, call for an investigation into organic basic salts of copper and their properties as pigments. The absence of recipes for certain pigments is also of interest. A copper resinate made by dissolving verdigris in a pine oleoresin was used so early as the close of the eighth century, yet no recipe has yet been found earlier than that given by Dr. Mayerne in the seventeenth century.

Very few recipes, and those of little value, are given for the preparation of madder lakes, yet fine madder lakes which have stood remarkably the test of time are found so early as the late fifteenth century, and it is difficult to decide how they can have been prepared. The use of madder as a dye was confined to certain dyers in Marseilles, and they may have possessed secrets which were unknown to the painter.

The publication of this book is singularly opportune, when we have at last in the Courtauld Institute a laboratory equipped for research on these lines. Mr. Thompson has provided for this work with a rich mine of material.

A. P. LAURIE.

Vasodilator Substances in Animal Tissues

Gefässerweiternde Stoffe der Gewebe
Von Prof. J. H. Gaddum. Eingeleitet von H. H. Dale. (Monographien zur Pharmakologie und experimentellen Therapie, herausgegeben von Philipp Ellinger.) Pp. xii+200. (Leipzig: Georg Thieme, 1936.) 18 gold marks.

THE basic problem can be stated by pointing out that in the animal body there is a central mechanism for cutting off the blood supply to the different organs; but, so far as present knowledge goes, no central mechanism for increasing it. How then is an active organ, for example, a particular group of muscles in the leg, to obtain a greater blood supply than it received when resting? It was formerly believed that the liberation of acid as the result of tissue activity caused local vasodilatation; it is now thought that vasodilatation follows the liberation of various bases such as histamine, adenosine and others not yet identified.

The old and the new views are linked by the probability that the actual liberation of the bases is a secondary consequence of acid formation. Not, be it observed, that the problem has been recognized and attacked as a problem directly. A series of attempts have rather been made to isolate from tissue extracts substances responsible for various physiological properties possessed by these extracts. Just as biochemical progress has come from the identification of substances having a characteristic colour reaction, so by identifying substances having a characteristic vasodilator reaction, pharmacological progress has followed. This work is both difficult and laborious and demands much experience of the pitfalls of pharmacological analysis. Prof. Gaddum's book is an extremely valuable account of the chemical and pharmacological properties of the substances which have hitherto been investigated. A great part has been the work of Sir Henry Dale and his very able collaborators, and it is due to his persistence that the subject has been extended so as to throw light on many other aspects of physiology. A stimulating introduction comes from Sir Henry's pen.

The book deals in succession with histamine, acetylcholine, adenosine and then with substances of unknown composition. The author then strains the title by including a chapter on the chemical transmission of nervous impulses, but this will be perhaps its most useful feature to those not working in the special field. The book is a fitting testimonial to Prof. Gaddum. Nothing seems omitted, opinion is not withheld, and when given it is fully supported by evidence; the writing is modest and precise. The best tribute one can pay to the German translation by Dr. Feldberg is that it is very easy to read, but one may make the comment that it is strange to find in German the first general account of work so largely done in Great Britain.

J. H. B.

A Text-Book of Inorganic Chemistry

Edited by Dr. J. Newton Friend. (Griffin's Scientific Text-Books.) Vol. 11 : Organometallic Compounds. Part 3 : Derivatives of Phosphorus, Antimony and Bismuth. By Archibald Edwin Goddard. Pp. xxviii+318. (London : Charles Griffin and Co., Ltd., 1936.) 20*s.* net.

VOL. 11 of Dr. Friend's "Text-book of Inorganic Chemistry" deals with organometallic compounds, and the author is Dr. Goddard. It is divided into four parts, the first dealing with derivatives of elements of Groups I to IV of the Periodic Classification of the elements, and the second part with derivatives of arsenic. The present volume describes the organometallic derivatives of the other elements of Group V, namely, phosphorus, antimony and bismuth, leaving the elements of Groups VI–VIII for Part 4, now in preparation.

The book under review is planned on simple lines. Thus the first two chapters deal with fatty and aromatic derivatives of phosphorus, followed by a chapter on miscellaneous phosphorus compounds; fatty and aromatic compounds of antimony, and organometallic derivatives of bismuth are described in the remaining chapters of the book. Of these six chapters, the last two deal with groups of compounds which have formed the subject of original researches by the author.

The wide range of the subject is shown by the fact that reference is made to 2,600 derivatives of phosphorus, 700 of antimony, and 100 of bismuth. The most interesting chapter is perhaps the one which deals with the miscellaneous compounds of phosphorus, since, when this element is used in the form of chloride to bring about a simple replacement of OH by Cl or $>O$ by Cl_2, it often gives rise instead to addition compounds, which can then be hydrolyzed to phosphinic acids. In this and similar ways the chemistry of phosphorus is extended, until it almost begins to bear comparison with that of nitrogen, with which it is also associated as an essential element of plant and animal life.

This important group of organic compounds has been dealt with by Dr. Goddard in the same efficient manner in which Dr. Sidgwick described the organic derivatives of nitrogen, in a volume which has unfortunately been out of print for some years. By doing so, he has not merely contributed an additional volume to a well-known text-book, but also has earned the gratitude of his colleagues by giving (perhaps for the first time) an adequate account of an unfamiliar section of organic chemistry.

The Medicine-Man of the American Indian and his Cultural Background

By Prof. William Thomas Corlett. Pp. ix+369+14 plates. (Springfield, Ill., and Baltimore, Md. : Charles C. Thomas ; London : Baillière, Tindall and Cox, 1935.) 22*s.* 6*d.*

AN unfortunate currency given to the popular term 'medicine man' to designate the shaman or priest-magician of the Amerindian tribes has given rise to much misunderstanding as to the true function of this important figure in the Indian social organism. Although the healing art comes within his province, his theory and practice are based on psychology and theology rather than on pathology and pharmacology. In fact, the cure of disease is not his primary function, but an incidental of his relation to the spirit world, in which he acts as the tribal specialist and go-between. Apart from the sweat-house, and a not very extensive acquaintance with simples, magic, which does not differ in essentials from the practices of other parts of the world, is the beginning and end of his diagnosis and treatment. The medicine man, like the shaman of the north-eastern tribes of Asia, to whom indeed he is closely related in many of his functions and attributes, is the spiritual guide of the tribe and its leader in emergency, in many instances holding a position analogous to that of the war chief.

Notwithstanding the basic identity of the conception of the medicine man's function throughout the North American tribes, there is no little variation in detail, both in the position they hold and in their methods of action. Dr. Corlett's purpose has been to place before his readers a conspectus of the evidence and to demonstrate the variations to be found in passing from one to any other of the areas of cultural differentiation into which the Indians of North America have been classified by anthropologists.

The Phenomena of Polymerisation and Condensation :

a General Discussion held by the Faraday Society, September 1935. Pp. vi+412. (London and Edinburgh : Published for the Faraday Society by Gurney and Jackson, 1936.) 22*s.* 6*d.* net.

THIS publication records the first symposium in Great Britain specially convened to deal with fundamental aspects of polymers, among which synthetic resins and rubber are important industrial examples. The volume will naturally appeal to those workers on plastics who appreciate the importance of a knowledge of the principles underlying formation of their products.

The first section employs the weapons of X-ray spectrography, mechanical properties and kinetics of chain formation in elucidating structures, and is concerned with general concepts of polymeride formation. In general, the latter term is used in the modern sense to imply substances containing repeated units of definite structure not necessarily identical with the starting materials. An attempt by Dr. W. H. Carothers to connect, in a mathematical manner, polyfunctionality with polymer formation, and a study by Dr. K. Meyer of an inorganic polymer from phosphonitrilic chloride, deserve special mention.

The second section contains more specific cases, among which is a most suggestive contribution by Dr. H. Staudinger on the so-called 'insoluble polystyrene'. Although papers on phenol-aldehyde, amide-aldehyde and acetylene products are included, it is an unfortunate, but perhaps unavoidable necessity, that gives such prominence to polystyrene, at the expense of those more complex materials which have formed of late years the basis of industrial plastics development.

N. J. L. M.

An Introduction to Contemporary German Philosophy

By Dr. W. Brock. Pp. xx + 144. (Cambridge: At the University Press, 1935.) 6*s*. net.

THE study of German thought, which has been so popular in Great Britain, has been encouraged lately by the introduction of German philosophy as an optional subject in the syllabus of a first degree in German in the University of London. The interest taken by this University in German studies is further exemplified by its invitation to Dr. Brock to give a course of lectures on German contemporary thought. The book under notice is a direct result of this invitation.

German humanism and the development of the separate sciences are considered to be the background of contemporary German philosophy. Two new philosophical movements have asserted themselves since Hegel: the first covers the numerous attempts towards a philosophical synthesis of scientific results, and the second concerns epistemological inquiries. Then Nietzsche and Kierkegaard have cast their shadow over subsequent thinkers as well as over their contemporaries. These Dr. Brock considers in turn with an objective though sympathetic mind. But their conflicting conclusions leave still undecided the position of philosophy among the determining factors in human life. It would have been interesting to analyse the intellectual factors which have brought German thought to that peculiar position in which it has to renounce its very freedom of action and expression. T. G.

Kursus der Kristallometrie

Von Prof. Dr. Victor Goldschmidt. Aus dem Nachlass herausgegeben von Dr. Hans Himmel und Dr. Karl Müller. Pp. viii + 167. (Berlin: Gebrüder Borntraeger, 1934.) 10 gold marks.

THIS is essentially a practical guide to crystal measurement, drawing and calculation based on the established methods of the Victor Goldschmidt school of crystallography.

Following the general introduction, which deals with the various methods of projection, single-circle goniometry, illustrated mainly by the Penfield contact goniometer, is simply described and two examples are given. This section occupies six pages.

The remainder of the book is devoted to two-circle goniometry and is divided into two parts. Part 1, which provides an admirable introduction to the methods, deals with the two-circle contact goniometer designed by the author. The procedure involved in crystal measurement, drawing and calculation together with the preparation of crystal models is fully discussed and examples from each of the six systems are given in full. Part 2 illustrates the use of the two-circle reflection goniometer and provides examples of more advanced studies of simple and twinned crystals.

This posthumous work of the late Prof. V. Goldschmidt bears the characteristic marks of care and attention to detail which all his work illustrated, and is a very complete and lucid guide to the crystallographic methods evolved in great part by the author.

Die Fermente und ihre Wirkungen

Von Prof. Dr. Carl Oppenheimer. Supplement, Lief. 4 (Band 1, Specieller Teil: Haupt-Teil 9–12). Pp. 481–640. (Den Haag: W. Junk, 1936.) 28*s*.

THE fourth part of this work has appeared with commendable punctuality. It deals with the polyases, which are the enzymes which split the complex carbohydrates, the nucleases, the amidases and the first sections of the proteases.

Now that we possess at least an approximate knowledge of the structure of the more complex carbohydrates, it should be possible to make progress also in regard to the enzymes which attack them: for example, the increasing study of the polyfructoses, of which there are apparently several besides inulin, may teach something about inulase. The same applies to such enzymes as lichenase, chitinase, cytase and pectinase, and this section, which gives also a brief indication of the latest views in regard to the structural formulæ of these polysaccharides, will be found to be stimulating.

Recent work has more or less cleared up the structure of the nucleic acids: their appropriate enzymes either convert the acids into nucleotides or these latter into nucleosides and phosphoric acid, or effect the final degradation of the nucleosides into a base and a sugar: there is still much to learn about these and the way in which they work.

The amidases are those enzymes which break the bond between carbon and nitrogen as, for example, in adenine and guanine. They include arginase, of which a good deal is known, also those enzymes which hydrolyze acid amides and lastly urease.

The protein section is of an introductory character.

Grundlagen der Quantenmechanik

Von Dr. H. Dänzer. (Wissenschaftliche Forschungsberichte: Naturwissenschaftliche Reihe, herausgegeben von Dr. Raphael Ed. Liesegang, Band 35.) Pp. xi + 163. (Dresden und Leipzig: Theodor Steinkopff, 1935.) 12 gold marks.

THIS brief but excellent introduction to quantum mechanics is likely to appeal much more to the mathematician than to the experimental physicist, for, as its title suggests, it deals rather with the fundamental ideas than with the applications of wave-mechanics to special problems. The treatment really assumes that the reader possesses a fairly good knowledge of mathematics, and the book should find a welcome from teachers of mathematical physics.

La spectroscopie appliquée

Par P. Swings. (Bibliothèque scientifique belge.) Pp. 188. (Paris: Hermann et Cie., 1935.) 15 francs.

ALL who are interested in the teaching or practice of spectroscopy will find this well-written and informative little volume of interest. In particular, the common errors which are encountered in connexion with spectroscope adjustments are discussed in some detail. The advantages and disadvantages of the various sources of light are also well considered, and it is clear that the author has made a profound study of the contemporary literature of the subject.

Cereals of Ancient Egypt and Mesopotamia

By Prof. John Percival

THE origin of civilization is intimately connected with man's discovery of the cultivation of the cereal crops, the grain of which has formed the most important part of the diet of civilized people from the earliest times down to the present day.

It requires but little reflection to realize that the lives of the millions of inhabitants of the villages and towns throughout the world to-day are dependent upon the unceasing toil of the farmer; were he to discontinue his efforts, the congested humanity of our great centres of population could not exist very long. It is, indeed, no exaggeration to say that the total loss of the cultivated crops of one, or at most, two seasons all over the world, would wipe out the greater part of the human race, and leave the towns and all they contain silent and derelict; the farmer is truly worthy of more respect and sympathy than he usually gets.

Who were the first farmers, where did they live and what were the crops which they grew, are questions of fascinating interest on which light is being thrown by the patient researches of archæologists. Historic records of man's activities take us back some four or five thousand years, at which time village settlements and towns were already established in Egypt and parts of Mesopotamia. Samples of the kind of grain forming, as now, the chief portion of the diet of the people, have been unearthed, and it is to these that I now refer.

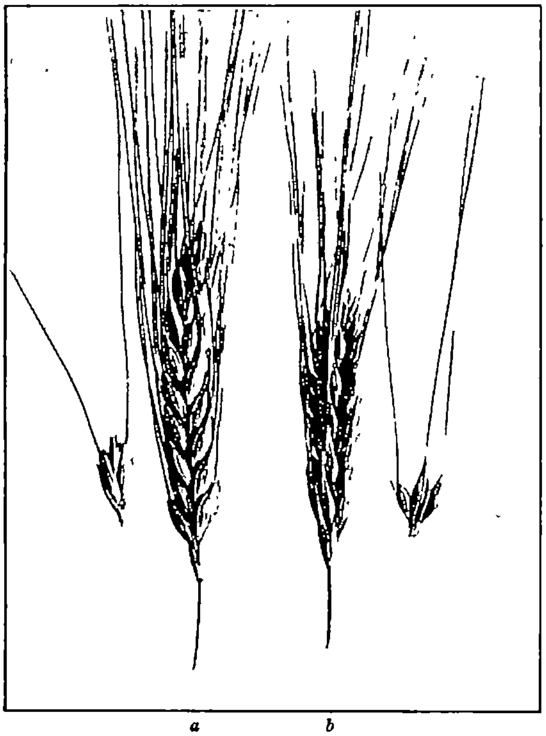

FIG. 1. *a*, Ear of modern Abyssinian Emmer, with spikelet. *b*, Ear of Bere barley, with triplet of single-grained spikelets (about half natural size).

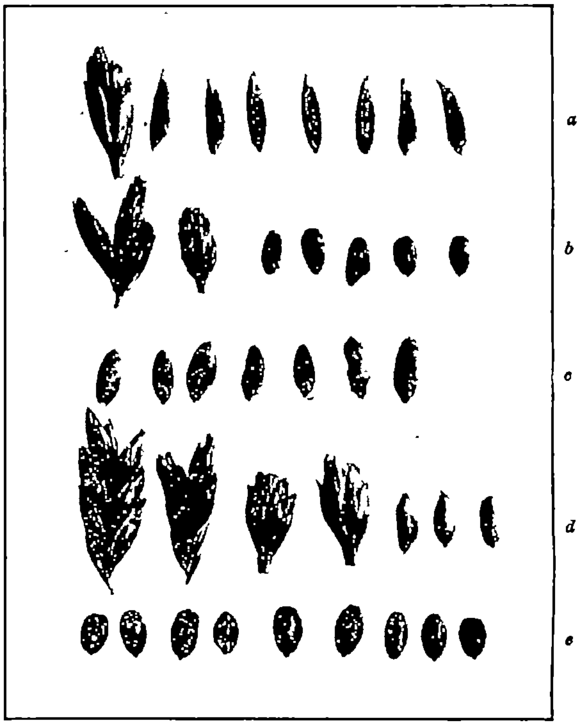

Fig. 2. *a*, Spikelet and grains of Abyssinian Emmer. *b*, Part of ear, spikelet and grains of Badarian Emmer, from Mostagedda (? 5000 B.C.) (Mr. Guy Brunton). *c*, Badarian grains of Emmer from Mostagedda. *d*, Portion of ears, spikelets and grain of pre-dynastic Emmer, from the Fayum desert. *e*, Naked wheat grains from pre-dynastic Fayum site (Miss Caton-Thompson) (all natural size).

From the earliest times in Egypt and in Mesopotamia, two kinds of cereal grains were cultivated, namely, wheat and barley. The wheat which was grown was a kind or race of this cereal known as Emmer (*Triticum dicoccum*). It was a very primitive kind of wheat, with flat ears having long awns or beards, like those of present-day barley (Fig. 1, *a*). Ears of Emmer when thrashed break up into short spikelets (Fig. 1), each of which contains two grains closely invested by the glumes or chaff, so much so that the naked grains for consumption can only be obtained free from the chaff by pounding the spikelets with a long pole

Upper [illegible] Dept

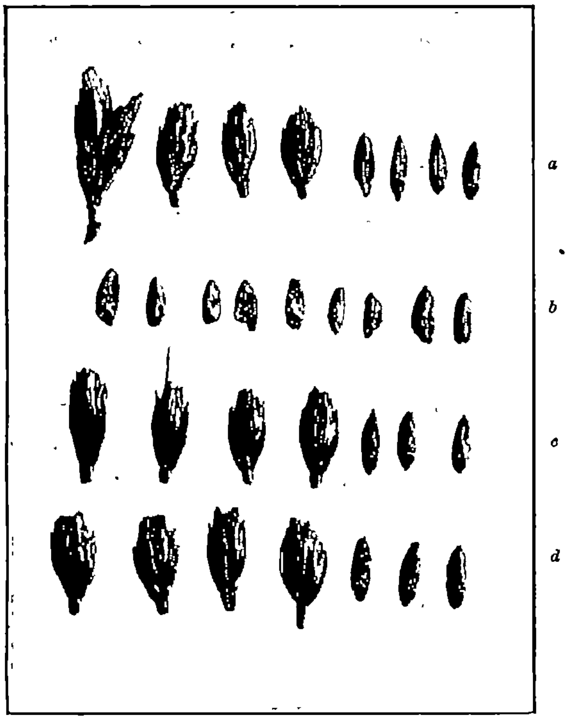

FIG. 3. *a*, Portion of ear, spikelets and grains of Emmer, from tomb of third dynasty, inside enclosure wall of step pyramid of Sakkara (about 3000 B.C.). *b*, Naked Emmer grains from underground gallery magazine, north side of Sakkara pyramid. *c*, Spikelets and grains of Emmer, from tomb of Tutankhamun (about 1400 B.C.). *d*, Spikelets and grains of Emmer from tomb of Eighteenth Dynasty (about 1500 B.C.) (all natural size).

in a kind of wooden mortar. The naked grains are narrow and pointed at each end, much narrower and less plump than the ordinary wheat of our fields to-day.

Emmer is still cultivated for human food in Abyssinia, parts of Russia and India, and in smaller amounts in north-west Persia, Serbia, south-west Germany and the Basque provinces of Spain. It is remarkable that many of the varieties of Emmer still grown are exactly similar in their specific characters to those cultivated by the most ancient Egyptians.

In addition to Emmer (*T. dicoccum*), several other different species of wheat are known with brittle ears which break up readily into short spikelets when thrashed; these are classed together as 'spelt' wheats, 'spelt' being in this case a generic term. Unfortunately, *one* of these has the specific name "Spelt" given to it, being called Spelt or Large Spelt (English), *Spelz* or *Dinkel* (German), *Epeautre* (French); its botanical name is *Triticum Spelta*. This wheat is a comparatively modern kind, quite unknown to the ancient people of Egypt, but Egyptologists in particular have frequently fallen into the error of translating the Egyptian term for Emmer by the word "spelt" and adding to it the name *Triticum Spelta* instead of *T. dicoccum*.

The ears of the other cereal, barley, are differently constructed from those of Emmer. In barley, three single-flowered spikelets grow close together on opposite sides of the axis of the ear; there are thus six longitudinal rows of spikelets. In the so-called two-rowed barley commonly grown in the fields of Great Britain, only the central flower of each triplet produces grain, giving rise to an ear with two opposite rows of grain. In Bere barley (*Hordeum vulgare*) and Six-rowed barley (*H. hexastichon*), all the flowers of the triplet of spikelets are fertile, and an ear with six rows of grain is produced.

All these kinds of barley are grown at the present time, the two latter being most frequently cultivated in Egypt and other countries bordering the Mediterranean. Both Bere and Six-rowed barley were cultivated in ancient Egypt and smaller amounts of the two-rowed form.

Whether the cultivation of Emmer preceded that of barley or vice versa has been the subject of controversy. A wild kind of Emmer grows in Syria, Palestine and regions near the Caucasus, and is generally accompanied by wild barley. Since there is no character in either which would suggest a preference for one of them, it would appear likely that both were selected contemporaneously by the first cultivators, probably

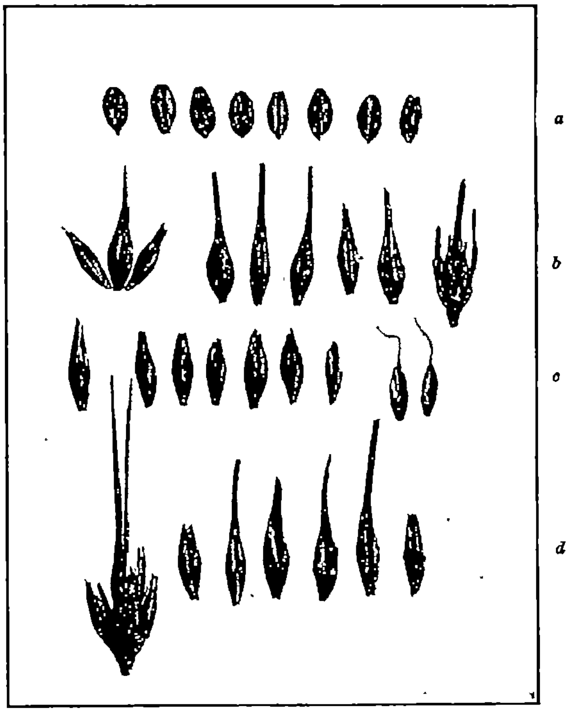

FIG. 4. *a*, Pre-Dynastic carbonized grains of barley, Fayum desert. *b*, Triplet of grains of Bere barley, single grains, and spikelet of two-rowed barley (?) Pre-Dynastic, from the Fayum desert. *c*, Grains of barley, and two 'seeds' of darnel (*Lolium temulentum*), from tomb of Third Dynasty, inside north enclosure of the step pyramid of Sakkara (about 3000 B.C.). *d*, Spikelets of barley of Eleventh Dynasty (Gebelien) (all natural size).

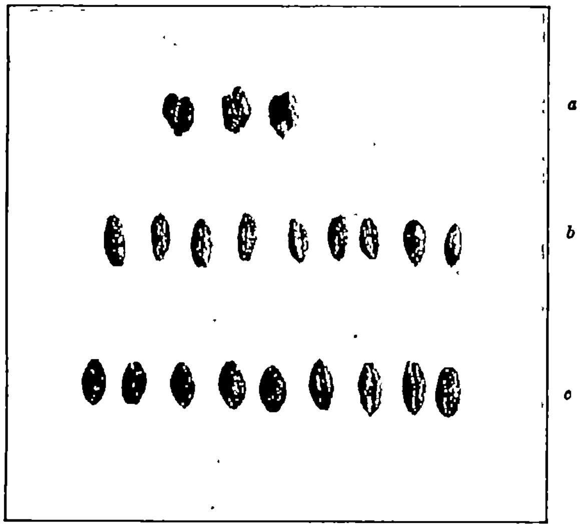

Fig. 5. *a*, Carbonized grains of three spikelets of Emmer, from grain room at Arpachiyah, near Nineveh (about 4000 B.C.). *b*, Carbonized grains of Emmer, and *c*, carbonized grains of barley from the same source (Mr. M. E. L Mallowen, 1933) (all natural size).

thousands of years before the large-scale farmers of the Egyptian dynastic periods. This view is supported by the fact that mixtures of Emmer and barley, and separate samples of the two, have been found dating from the earliest times.

All these ancient grains, whether taken from underground pits, storehouses, tombs or vessels within the latter, are more or less carbonized. Naked grains generally exhibit complete carbonization, becoming changed into charcoal; their appearance suggests the action of fire, and they are often erroneously described as charred or burnt.

The change from the normal to carbonized grain is, however, a natural process which takes place at ordinary temperatures. The carbohydrates cellulose and starch, of which the cereal grains are largely composed, consist of carbon united with the elements of water; under certain obscure conditions, both become slowly dehydrated, leaving behind only the carbon.

The carbonization of complete spikelets is very much less marked than naked grains. The chaff is more resistant to dehydration, and usually appears dark brown in colour. The grains within such spikelets often show little change; the form of the grain, the hairs at its apex, are but slightly altered, and the starch grains in the endosperm retain their shape and reaction to iodine. The proteins of the endosperm are, however, completely decomposed, and the embryo is always disorganized and quite incapable of germination.

For more than a hundred years, samples of wheat and barley have been taken from tombs in Egypt, but only within comparatively recent times have trustworthy records been made of the archæological horizon from which the samples have been derived, and the age of many of the earlier finds cannot now be determined. During the last few years, however, much well-authenticated material has been submitted to me for examination, and it is with this that I deal here.

Among the most ancient specimens of cereal grains hitherto discovered in Egypt are those found by Mr. Guy Brunton at Badari (1923–34) and at Montagadda, Middle Egypt, in 1928. Fragments of ears and spikelets were obtained, together with carbonized grains of Emmer (*T. dicoccum*) and grains of Bere barley (*Hordeum vulgare*) (Figs. 2 and 4). The Badarian folk were growing both these cereals at a date antecedent to the predynastic period, which according to some Egyptologists extended from about 5000 B.C. down to 3400 B.C. when the first of the Egyptian dynasties was established. How much earlier than this these samples were harvested cannot be accurately assessed; some authorities have placed them as early as 10,000 or 15,000 B.C.

Another series of excellent samples belonging to the pre-dynastic period was obtained by Miss Caton-Thompson, in the Fayum desert, northwest of the Birket Qurun lake. A number of small straw-lined granaries or pits was discovered, in several of which were portions of typical ears of Emmer with grains (Fig. 2, *d*), as well as grains of Bere barley (Fig. 4, *b*). In some of the pits were found completely carbonized grains shorter and plumper than those of typical Emmer. Whether these are modified Emmer grains cannot be definitely settled, for the exact determination of the species of cereal grains when carbonized presents great difficulty, since the amount of

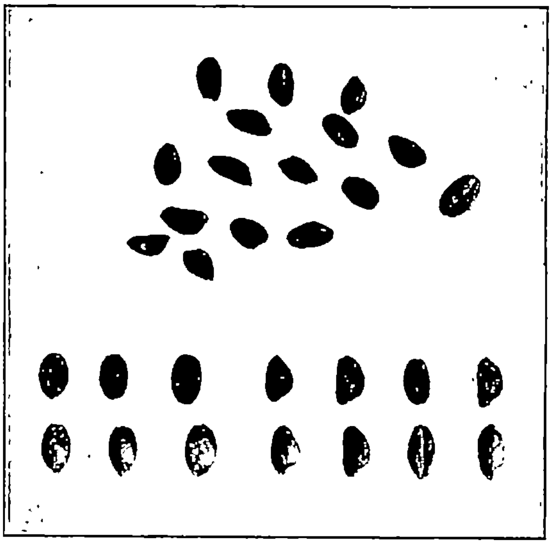

Fig. 6 Upper group random sample of grains of wheat from a vase on the site of a Sumerian house at Jemdet Nasr, near Kish (3500 B.C) (Prof. Langdon) First row of lower group selected carbonized grains from the sample. Second row of lower group. grains of modern Rivet wheat (*Triticum turgidum*) (natural size).

change in the size and form of the grains which appears in some cases to accompany carbonization is not accurately known.

Very numerous examples of grain from Egyptian tombs of later date are available (Fig. 3). These are invariably samples of Emmer and barley, and for several thousand years down to the end of the dynastic period, no other form of wheat than Emmer was cultivated in Egypt.

The dryness of Egypt has greatly contributed to the excellent preservation of all kinds of objects. In Mesopotamia, however, the other great centre of early civilization, the climate and damp soil have led to the destruction of most cereal grains and other plant remains, and very few specimens of grain from this region have been recovered.

From literary evidence, Hrozny concluded that the two chief cereals of ancient Babylonia were Emmer and barley, exactly as in Egypt, Emmer predominating at the earlier dates.

Two samples of great importance have been submitted to me for examination. One of these was found in 1933 by Mr. M. E. L. Mallowen in a granary during excavations of a prehistoric site at Arpachiyah, four miles east of Nineveh. Carbonized grains of barley, and a primitive, small type of Emmer were present (Fig. 5). These are the earliest grains hitherto discovered in Mesopotamia, belonging to a period 4000 B.C. or earlier. The other sample, sent by Prof. S. Langdon, of Oxford, was taken by Mr. Henry Field (U.S.A.) in 1926, from a vase on the site of an ancient Sumerian house at Jemdet Nasr, a few miles north of Kish.

Only grains of wheat were present, and these completely carbonized. They were of large average size, with blunt tips and the prominent dorsal hump characteristic of varieties of Rivet wheat (*Triticum turgidum*) (Fig. 6) which belongs to the Emmer group. I gave an account of the sample in NATURE of February 19, 1927. I consider that these grains represent an advance on the earliest forms of Emmer, resembling some superior types of Emmer now grown in Abyssinia, which are sometimes classed as Rivet wheats.

Mr. O. F. Phillips (U.S.A.) has expressed the opinion that these Kish grains are a kind of Club wheat (*Triticum compactum*), but I unhesitatingly regard this view as erroneous. There is no evidence that any wheat of the bread wheat group to which Club wheat belongs was known in any part of the world for some thousands of years after the date attributed to the Kish sample.

Mr. Henry Field records the discovery of barley grains at Jamdet Nasr, but these I have not seen.

It is hoped that archæologists will look for and carefully preserve all samples of grain which they may unearth in the investigation, paying special heed to fragments of ears and chaff, for these are of importance in the correct determination of the race or species to which they belong.

Biogeography and Ecology of North African Birds and Mammals

THE animal population of the northern parts of the African continent is of exceptional interest to a biologist, both by reason of the great similarity of the conditions in coastal areas to those of southern Europe, and by the striking contrast provided by the Sahara, with its extreme desert regime and highly peculiar fauna. While the fauna of North Africa in its entirety remains still very inadequately explored, our knowledge of at least two groups, birds and mammals, is sufficiently advanced for a comprehensive survey of the fauna. Such a survey is provided in a recent memoir by M. Henri Heim de Balsac*, who has based it not only on all the available literature, but also on personal explorations carried out over many years.

A careful analysis of the mammalian population of the coastal and mountainous Berberian zone reveals the somewhat unexpected fact that its relationship with the European fauna is not so close as is usually assumed. Apart from bats, three quarters of the species composing the Berberian mammalian fauna cannot be considered European, and are mostly Ethiopian in origin. Bats in this respect approach the birds, among which the majority are European; but there is a considerable proportion of unmistakable tropical forms. Since palæontological studies have shown a still lower proportion of European forms in North Africa in the earlier stages of the Quaternary period, it appears impossible to retain the idea of any post-Pliocene connexion of Europe with Africa. On the other hand, an exchange of populations with palæarctic Asia, through Libya and Egypt, must have existed until the middle of the Quaternary (Rissian) period. The Atlantic islands (Azores, Madeira, Canaries) are populated by relics of the Tertiary Mediterranean fauna, and did not play any prominent part in the origin of the Quaternary fauna of Berberia.

---

* Biogéographie des Mammifères et des Oiseaux de l'Afrique du Nord. (Supplément xxi au *Bulletin Biologique de France et de Belgique.*) Pp. 447+7 plates. (Paris: Press Universitaires, 1936.) 125 francs.

The northern limit of the Saharan zone depends on humidity, and the isohyet of 200 mm. per annum coincides almost exactly with the limits of the distribution of the desert fauna. The mammalian fauna of the Sahara is almost entirely tropical, mostly Ethiopian, in its origin, and even amongst birds the vast majority are non-palæarctic. It is, therefore, impossible to continue to include Sahara in the Palæarctic region, as is usually done.

A number of urgent problems of desert ecology are discussed in the second part of the memoir, comprising twelve chapters. There is a mass of original information, often leading to deductions which may be unorthodox, but are well supported by first-hand evidence. The distribution of mammals is very little influenced by the absence of water, since all of them are able to do without drinking, being satisfied with the water obtained from food. The same, however, is observed in mammals elsewhere, and cannot be considered as a special physiological adaptation. Among birds, only a few grain-feeding species (Pteroclidæ, etc.) cannot live without drinking, while all those with mixed diet can do so. No special adaptations exist in desert mammals for protection against powerful insolation, since the vast majority of them are nocturnal in their habits, and many pass the day underground. In birds, which are exposed to the sun, no special adaptations in behaviour have been noted.

As regards morphological adaptations to desert environment, some of the classical text-book examples do not withstand serious criticism. Thus, a statistical study of the structure of the feet in desert mammals and birds shows that, contrary to accepted opinion, there is no special dominant type of structure which can be regarded as adaptation to the environment. On the contrary, there is a great variety of structures, and some of them appear to be singularly ill-adapted to the particular habitat. Similarly, the hypertrophy of external ears considered by many authors as a typical feature of desert animals is actually not a general feature. As regards the great development of bullæ tympanicæ observed in the large majority of desert mammals, it appears to be a real response to the environment, but its physiological and biological significance is wholly obscure, and various hypotheses as to its presumed rôle rest on a desire to prove its usefulness to the animal, rather than on facts.

Again, a thorough discussion of the vexed problem of the coloration of desert animals does not permit the author to subscribe to its classical explanation as a protective device developed by selection. Both the hypertrophy of the bullæ tympanicæ in desert mammals, and the dilution of pigments, with the preponderance of phæomelanines and almost complete absence of carotinoids, are regarded by the author as characters which developed in strict dependance on the dryness of the environment, acting on the organism either directly, or indirectly.

Every ecologist and general biologist will find in this memoir, the contents of which are very inadequately expressed by its modest title, a store of original ideas, supported by abundant and fresh data of biogeographical, ecological, anatomical and physiological order.

B. P. UVAROV.

Blackpool Meeting of the British Association

ALL signs point to a full and interesting meeting of the British Association on September 9–16 in its new surroundings. The work of the Association, wide enough in all conscience, has been, of recent years, taking on a still wider character. The man of science is realizing to-day, as he never realized before, that he is, as man of science, a citizen of a great community; that he is a power in that community; and that he can forge weapons of a potency, for good and ill, such as the world has never yet known. The destinies of the future civilizations are in his hands, more than in those of any other class; and it is for him to see that the knowledge which he presents so freely to his fellows is used for weal, and not for ill.

To that end, it is necessary to study, critically and minutely, the effects of the advances of science on the well-being of the community. Most of us are content to indulge in that study, so long as it is a matter of handing out bouquets; but the gifts of man to mankind may be evil as well as good, and it is precisely those possibilities of evil which demand most careful study. The new policy of the Association, of starring in its programme those items which deal with aspects of knowledge the repercussions of which on the welfare of the community are direct and important, marks an important step in the history of the Association; it is to be hoped that it will remain a permanent feature of the programme.

The subject of the presidential address (the impact of science on society), the titles of the sectional presidential addresses, and the principal topics of discussion have already been announced in an article which appeared in NATURE of May 9 (p. 766). To these we may now add the series of public lectures and lectures to children. The series is as follows:

PUBLIC LECTURES.

Lytham St. Annes. Dr. Olaf Bloch: "The Scope of Photography".
Blackpool South. Dr. W. F. Bewley: "Science and the Glass-house Industry".
Preston. Prof. J. L. Myres: "Who were the Greeks?"
Southport. Sir James Jeans: "Some Recent Advances in Astronomy".
Poulton-le-Fylde. Mr. P. A. Francis: "Applications of Science to Poultry Farming".
Fleetwood. Prof. C. M. Yonge: "Common Shore Animals".
Thornton Cleveleys. Dr. D. F. Harris: "Joy in Scientific Discovery".
Preston. Prof. Allan Ferguson: "Splashes and what they Teach".

LECTURES TO SCHOOL CHILDREN.

Brigadier H. S. L. Winterbotham: "How Maps are Made".
Mr. D. Seth Smith: "Favourites of the London Zoo".

Evidently the public lecture, whether to a senior or to a junior audience, is becoming an increasingly important feature of the annual meeting. It is possible that this impressive list of lectures is still incomplete, as applications are still coming in from some of the East Lancashire towns.

The Evening Discourses, to be delivered by Mr. C. C. Paterson and by Capt. F. Kingdon Ward, will deal with "Science and Electric Lighting" and with "Plant-hunting and Exploration in Tibet". These discourses are open to members only.

Some of the sectional excursions and the social events have already been announced. The Mayor and Mayoress of Blackpool (Alderman W. Newman and Miss Newman) invite members to a reception in the Winter Gardens on Thursday, September 10. The headmaster of Rossall School (Mr. H. G. M. Clarke) will entertain four hundred members at a garden party at the School on Tuesday, September 15. The Rotary Club will hold a luncheon on Thursday, September 10, when the president will address the members and their guests. The Official Service will be held at St. John's Parish Church on Sunday, September 13, when the Right Reverend the Lord Bishop of Blackburn will preach the sermon.

Thirty sectional excursions and visits have been arranged, of geological, botanical, antiquarian, engineering and educational interest. Their range in space is as wide as their range in subject. A visit to the Amusement Park stands cheek by jowl with an excursion to the Lake District, and a visit to the open-air swimming bath hard by an excursion to Garstang, Furness Abbey and the Southport Sand Dunes, Stonyhurst and Rossall, Fleetwood Fish Docks and the Fylde Farms. The members of the Association will indeed have enlarged their experiences by the time that the annual meeting draws to its close.

Obituary

Sir Henry Wellcome, F.R.S.

EARLY on the morning of Saturday, July 25, there passed away, at the ripe age of eighty-two years, a unique personality, whose activities ranged from archæological and geographical exploration to the creation of a great manufacturing business, and whose interests included such diverse matters as the collection of ancient manuscripts, the social welfare of native races and the provision of funds for fundamental research in those sciences on which the progress of medicine depends.

Sir Henry Wellcome was born in Wisconsin and, as the son of a frontier missionary, spent his childhood among Dakota Indian tribes. A boy whose earliest experiences included that of organizing the casting of rifle bullets for the defence of a settlement of whites, and of assisting his uncle—a well-known frontier surgeon—in treating the wounded in the Sioux War in Minnesota, was obviously well-equipped for an interesting career. He chose pharmaceutical chemistry as a vocation, and passed a period of study in Chicago and Philadelphia, where he took his diploma. His life-long interest in travel began to show itself at this stage, and he visited most parts of North America and spent some time in South America in the study of cinchona distribution in its native habitat, a subject in which his life-long interest was again manifested in the tercentenary celebration of the discovery of cinchona, which he organized in London in 1930.

Having given full play to the romantic side of his nature in these *Wanderjahre*, Wellcome looked round for a suitable centre for the exercise of his practical bent towards the pharmaceutical side of chemical industry and chose London as his future home, and here in conjunction with the late Mr. S. M. Burroughs he established in 1880 the firm of Messrs. Burroughs, Wellcome and Co. for the manufacture of fine chemicals and pharmaceutical products. The business was a success from the beginning; its products are known all over the world, and in addition to the chief works at Dartford, the firm now carries on operations in New York, Montreal, Sydney, Cape Town, Milan, Shanghai, Bombay and Buenos Ayres and has agencies in most of the world's great commercial centres.

The activities thereby engendered were not enough for Sir Henry Wellcome, and he soon began to use his resources in furtherance of the benevolent and scientific projects he had at heart. He founded at Dartford a club and institute with a park and ground for field sports, and in this and other ways spent large sums in providing technical instruction and means of mental and physical recreation for the staff and work people. In 1894, the Wellcome Physiological Research Laboratories were started, and two years later the Wellcome Chemical Research Laboratories were opened. In 1913 the Wellcome Bureau of Scientific Research was founded with the triple duty of controlling the various research laboratories already in operation, acting as a centre of information on scientific medical matters and to conduct research in biological subjects affecting the progress of medicine. Associated with it are the Entomological Field Laboratories and the Medical Museum, the latter a boon to students and remarkable for the wealth of its pathological material and the ingenuity of its illustrative methods. Sir Henry's latest and most striking gift is the magnificent building of the Wellcome Research Institution, which was described in NATURE of December 5, 1931, p. 974, and in which the organizations referred to above, with the exception of the Physiological and the Entomological Field Laboratories, are now housed.

For the greater part of his life, Sir Henry Wellcome had collected books, manuscripts, pictures and materials of all kinds illustrative of the customs and habits of primitive man and the beginnings and progress of pharmacy, medicine and surgery. These formed the nucleus of the Historical Medical Museum organized in 1913 in premises in Wigmore Street, where it rapidly outgrew the accommodation available. Of all his projects for the near future, the one nearest to the founder's heart was probably to see these cherished treasures displayed in the exhibition galleries designed for them in the new building, and it is a matter of keen regret to his friends that he did not live to see the completion of this scheme. Sir Henry's other interests can only be referred to briefly. For some years he conducted personally archæological explorations in the Upper Nile regions, discovering and excavating several important ancient Ethiopian sites, and since 1932 he has provided funds for the excavations at Tell Duweir (Lachish) of which an account appeared in NATURE of July 18, 1936, p. 135. He gave generously in funds and medical equipment to expeditions for geographical exploration, and his friendship with H. M. Stanley and his deep interest in Africa led among other things to the foundation of the Lady Stanley Maternity Hospital in Uganda, and the establishment in 1900 of Tropical Research Laboratories at the Gordon Memorial College, Khartoum.

In recent years, Sir Henry Wellcome received numerous honours and marks of appreciation of his services to research in medicine and its allied sciences. In 1932 he was elected a fellow of the Royal Society and an honorary fellow of the Royal College of Surgeons. In the same year he was created a knight, and in 1936 he received the Cross of the Officier of the Legion of Honour from the President of the French Republic, and he also had conferred on him, for outstanding services to Spain, the decoration "Comendador de la Orden de la Republica".

By the death of Sir Henry Wellcome, the world loses not only a great, but also an effective giver, for his benefactions were the outcome of a knowledge of the real, but not always obvious, means for the betterment of mankind.

Mr. F. C. Lewis

MR. FRANCIS CHARLES LEWIS was one of five men who unfortunately met their death through an explosion at the Research Department, Woolwich, on July 8. Born at Barry, South Wales, in 1894, he was educated at the Woolwich Polytechnic and Cardiff Municipal Secondary School. He studied at the University College of South Wales and Monmouthshire, Cardiff, graduating B.Sc. (Wales) in 1915. He then joined the staff of Messrs. Nobel's explosives factory at Pembrey, where he later superintended the manufacture of trinitrotoluene. In 1918 he became a member of the Royal Flying Corps, and shortly after the Armistice was appointed technical research chemist by Messrs. British Dyestuffs, Ltd.

In 1921, Mr. Lewis was appointed research chemist on the staff of the Explosives Branch of the Research Department, Woolwich, where his work has been almost entirely concerned with the application of high explosives to the requirements of the fighting services and with improvements in the methods of using these explosives to obtain the highest efficiency. This has included both explosives already in use and new explosives. Research of this type naturally calls for careful precautions in all its stages, and appropriate safeguards are applied to minimize the risks. These precautions have been generally successful, as is shown by the fact that the Explosives Branch has had only one previous fatality due to explosion since it came into existence in 1901.

Mr. Lewis's work has been of great value and his experience of high explosives has greatly assisted in the progress of the work. His loss will be much felt by his colleagues and friends. Mr. Lewis was married in 1920, and leaves a widow and four children.

G. R.

News and Views

Chronology of Early Man and Cultural Associations

IN his recent presidential address to the British Speleological Association (see NATURE of August 1, p. 194) Sir Arthur Keith, when arguing for a parallel evolution in the development of modern races from primitive ancestral forms in their respective continental areas, demonstrated the connexion between the Australian and *Pithecanthropus* of Java, with the aid of mid-Pleistocene Solo man as the connecting link between the early Pleistocene *Pithecanthropus* and the late Pleistocene form of that region, Wadjak man. There would now appear to be a possibility that the chronological position of the undoubtedly archaic form discovered in the gravels of the Solo river at Ngandong, Java, in 1932, may be called in question. In another column of this issue of NATURE (see p. 293) reference is made to a communication from Dr. P. van Stein Callenfels, the distinguished Dutch authority on the archæology of Indonesia, appearing in the current issue of *L'Anthropologie*, in which he points out that the cultural associations of Solo man, harpoons and axes of stag horn, are such as in a European context would denote an antiquity of not more than nine or ten thousand years. While the early dating of Solo man has been generally accepted hitherto, if, as is stated, these artefacts are apparently beyond question contemporary with the human relics, this would appear to demand re-examination of the geological data. If further consideration supports Dr. Callenfels' argument, like the evidence of the Swanscombe skull in relation to the position of Piltdown man (see NATURE, August 1, p. 200), it would suggest that the current phylogenetic scheme, while valid as a logical classification, is an uncertain guide to chronology, and that the evolution and descent of man has been a far more complex process than has been demonstrated hitherto.

Spiritual Healing

AT the Methodist Conference held at Newcastle in July, the report of a Committee on Spiritual Healing was read by the Rev. Leslie D. Weatherhead (*Methodist Recorder*, July 23). He declared it to be an interim report only, and expressed the hope that the Committee would be reappointed. The report is cautious in tone, recognizing that the subject is full of difficulties. The trouble from the scientific point of view is that what appear to be like causes do not necessarily produce like effects. "We pray for one man and he gets better; we pray for another and he does not—and we don't know why in either case." Of course, in healing, the individual factor is the important one, and this makes scientific generalizations almost impossible. The only thing to do, presumably, is to record a large number of cases as accurately as possible, and to extract from them whatever may seem to establish some sort of a regular law of behaviour. Or, as the report puts it: "the work which lies before students of this subject must include research into those conditions under which those energies which sweep through personality may be set free to do their work." The report wisely says: "We felt all along that a method is not less a manifestation of the Divine because it is understood." As for "orthodox" medical science, "We believe no method [of spiritual healing] is to be welcomed which brushes aside as irrelevant the amazing findings of modern medicine and surgery." It is indeed all to the good that religious bodies such as the Methodist Church should interest themselves in the systematic study of the psychological causes of physical health and sickness, and the report of this Committee is for that reason important.

J. C. Loudon and the Waterloo Beeches

REFERRING to the note in NATURE of August 8 (p. 237) in which this excellent story was mentioned, a correspondent points out that there are many variants of it extant. Sir William Fraser's version, which is by far the most detailed, bears all the signs of study of the original sources. It would spoil the story to condense it; let the worthy baronet tell it in his own inimitable, if stilted, fashion.

"The Duke of Wellington . . . received a letter . . . from the eminent landscape designer and great authority on botanical matters, J. C. Loudon. It was . . . to this effect:

" 'My lord Duke: It would gratify me extremely if you would permit me to visit Strathfieldsaye, at any time convenient to your Grace, and to inspect the Waterloo beeches. Your Grace's faithful servant, J. C. Loudon.'

"The Waterloo beeches were trees that had been planted immediately after the battle of Waterloo; as a memorial of the great fight. The Duke read the letter twice, the writing of which was not very clear; and, with his usual promptness and politeness replied as follows; having read the signature as 'C. J. London' instead of 'J. C. Loudon':

" 'My dear Bishop of London, It will always give me great pleasure to see you at Strathfieldsaye. Pray come there whenever it suits your convenience, whether I am at home or not. My servant will receive orders to show you so many pairs of breeches of mine as you wish; but why you should wish to inspect those that I wore at the battle of Waterloo is quite beyond the comprehension of Yours most truly, Wellington.'

"This letter was received, as may be supposed, with great surprise by the Bishop of London. He showed it to the Archbishop of Canterbury, and to other discreet persons: they came to the melancholy conclusion that the great Duke of Wellington had evidently lost his senses. The Bishop of London (Blomfield) declared that he had not written to the Duke for two years; and to receive this extraordinary information puzzled the whole Bench of Bishops."

So far Sir William Fraser, whose account may be regarded as authoritative. Fraser (1826–98, Eton, Christ Church, and 1st Life Guards) worshipped the memory of Wellington with a devotion that almost reached fanaticism; his "Words on Wellington", from which this account is taken, is one of the most remarkable collections of sayings and doings that have ever been recorded concerning one individual—remarkable not only in the variety of its Wellingtoniana, but in the insight which it gives into the character of its compiler. The book is long out of print, and has a certain historical value. The author carried out a first-rate piece of detective work, of which he gives a full account, in his identification of the scene of the Duchess of Richmond's famous ball on the eve of the battle of Waterloo.

Scientific and Industrial Research in Australia

THE Australian Government has announced that the work of the Council for Scientific and Industrial Research is to be extended in the interests of secondary industry generally. Since its establishment in 1926, the Council has deliberately restricted its attention to problems of the primary producing industries, though no such restriction is imposed upon it by the Act under which it is constituted. It has always been assumed that an extension was only a matter of time in view of the contraction of world markets for primary products and the consequent pressure to increase the home market by expanding secondary industries. A recent decision to establish aircraft and motor production in the Commonwealth has intensified a growing demand for an extension of national scientific research, and an influential committee, including leading engineers and industrialists, is now at work preparing a definite scheme of work. Existing institutions will be utilized wherever possible, but it is fully recognized by the Government that considerably increased financial obligations must be carried by it. A first step is to establish an agency for the maintenance of accurate fundamental standards of measurement and for the testing of master gauges for controlling precision manufacture. It is intended that in all developments intimate contact shall be maintained with, and guidance sought from, established British institutions engaged on work of the same type.

Luminous Phenomena on the Sea during a Thunderstorm

THE occurrence, during a tropical thunderstorm between Singapore and Bangkok on the morning of May 21, 1936, of a diffused white light over the surface of the sea, pulsating at regular intervals of about two to the second, so that the ship seemed to be sailing through waves of light and darkness, was referred to by a correspondent in *The Times* of June 26. The phenomenon is said to have continued for about half an hour. Another correspondent referred to a similar phenomenon in the Persian Gulf in March 1908, when waves of light were observed wheeling round the ship. Both these phenomena would appear to have been due not to electrical conditions but to phosphorescence. A description and sketch of a "Phosphorescent Wheel" near Sumatra (with an interval of about one second between the waves of light) is given in the *Marine Observer* of the Meteorological Office of November 1926; waves of light with an interval of half a second were observed on October 27, 1924, at 1 a.m. near Krakatoa Island (*Marine Observer*, October 1925); streaks of luminescence, observed in January 1927 in the Equatorial Atlantic, were practically parallel with the wind, which was south-east, about force 4 (*Marine Observer*, January 1928). These observations indicate that phosphorescence is not uniform over the wave profile, and consequently streaks of light will appear to an observer on board ship to move as the ship moves relative to the waves. Phosphorescence is most readily observed on ripples or on the breaking crests of waves, and while no one has yet worked out in detail the conditions under which the streaks will appear, the period of pulsation, which is reported as 0·5–1 second, is probably equal to the interval of time between the passage of the ship over successive waves.

Lightning and Atmospherics

IT is now generally agreed that the majority, if not all, the atmospherics encountered in radio communication originate in lightning flashes. When the storm is close to the receiver, it is possible to identify the stronger atmospherics with the neighbouring flashes. In a recent communication, Mr. P. F. Fyson, Langherne House, Rushwick, Worcester, claims to have observed that the atmospheric crackle produced on a broadcasting receiver was heard before the lightning flash which caused it was perceived visually. If this difference in the perception of the two effects is real—it obviously needs verification by other observers—it would appear on first consideration that the human eye is rather more sluggish in its operation than the ear; and Mr. Fyson suggests that this may be due to the time required for the chemical change in the retina to affect the optic nerve. An alternative explanation, however, may be found in the fact, which has arisen from recent research on lightning, that an intermittent electrical discharge appears to precede the actual main lightning flash. It is possible that this discharge may be invisible and yet may be capable of producing audible effects on a wireless receiver. These sounds may thus be heard a very short time before the visible flash was observed.

Champollion and Hieroglyphics

In "Science News a Century Ago", in NATURE of August 8 (p. 257), an extract appears from the *Athenæum* describing an obelisk erected to the memory of Champollion, and bearing the inscription "To the memory of F. J. T. Champollion, who first penetrated into the mysteries contained in the writing and monuments of ancient Egypt. . . ." A correspondent has pointed out that, even allowing for the generosity of interpretation of a 'lapidary inscription', Champollion has no claim to the honour of first penetrating into the mysteries of the writing of ancient Egypt. That honour, beyond all question, belongs to our versatile countryman, Thomas Young. In 1819, Young published an article, "Egypt", in the supplement to the "Encyclopædia Britannica", in which he gave a list of *alphabetic and syllabic characters*, an article which has been described by Sir E. A. Wallis Budge as "practically the foundation of the science of Egyptology". In 1821, two years later, Champollion published a treatise in which he shows not the slightest trace of knowledge of anything alphabetic in hieroglyphic or hieratic characters; Champollion's publication of an alphabet dates from 1822. Concerning Champollion's alleged attempt to suppress his unfortunate work of 1821, we need say nothing here; the whole story of the Rosetta Stone and the decipherment of the hieroglyphic characters was discussed some years ago in an article in NATURE (April 30, 1932, p. 638). It is sufficient here to say that the inscription on the tablet to the memory of Young in Westminster Abbey states no more than the bare truth when it describes him as the one who "first penetrated the obscurity which had veiled for ages the Hieroglyphics of Egypt".

Recent Acquisitions at the Science Museum

AMONG the objects recently placed on exhibition in the Science Museum, South Kensington, is a model of the complete lay-out for a 120-ton 10,000 horse-power Mond gas producer plant with ammonia recovery apparatus which has been lent by the Power-Gas Corporation, Ltd. Mr. Edward J. Willis, an American authority on astronomical navigation, has sent from the United States an example of a navigating machine which was invented by him and constructed at a cost of about £300. The machine solves problems in spherical trigonometry connected with navigation. An example of Selling's calculating machine which has long lain neglected in the stores of the Imperial College of Science and Technology has been lent to the Museum for exhibition. The machine was invented fifty years ago and made ingenious use of the 'lazy tongs' mechanism in order to perform multiplication and division. A representative selection of fourteen stone (chert) weights and a plaster cast of a fragment of a linear measure, all found in excavations at Mohenjodaro, Harappa, and elsewhere in northern India—relics of a civilization of c. 3250–2750 B.C., that formed great cities along the Indus valley, contemporaneous with the ancient Egyptian first to fifth dynasties, and the ancient Sumerian kingdoms in Mesopotamia—have been presented by the Archæological Survey of India.

Frontier System in Roman Scotland

A FURTHER effort to settle the question of the number and character of the occupations of the Roman fort of Birrens, near Ecclefechan, Scotland, is being made by excavations now proceeding in charge of Mr. Eric Birley, of the University of Durham. The problem to be solved is whether the occupation of the fort was part of the organization of the Antonine Vallum, as Sir George Macdonald has suggested, or whether it is to be related to Hadrian's Wall, as the Dere Street forts to the east recently have been shown to be by Mr. Ian Richmond's excavations. Two periods of occupation separated by a destruction were demonstrated in 1925 by excavation, but the examination of the stratification was not, nor was it intended to be, exhaustive. Search for further evidence is now being made, and with this object excavations are proceeding at two points down to the subsoil for a thorough examination of the stratification and the pottery. Up to the present, a section in the *retentura* of the fort, it is reported in *The Times* of August 10, has shown that a wooden building and two of stone preceded the two periods, of which evidence was found in excavations made in 1895. The wooden structure is assigned to the latter part of the first century and it is said that traces of Agricola have been found; while the two stone periods which follow are thought to belong to the Antonine occupation. Under the earlier of the two periods previously known, two vessels have been discovered, for which there are parallels from Hadrian's Wall. A second excavation in the *prætentura* has been more fruitful as a source of pottery and other finds, including a large piece of a cut-glass bowl, of which a fragment was found in 1895. Excavation at the west gate has exposed what is described as "the worst Roman masonry so far found in Scotland".

Archæological Finds in Iraq

DR. HENRI FRANKFORT'S assiduity in making known to the public at an early date any points of special interest arising out of the excavations of which he has been in charge, season by season, is worthy of all commendation, especially since he became field director for the Oriental Institute of the University of Chicago at Tell Asmar, the ancient Eshnunna. The important and extensive operations of the Oriental Institute in the field of the Ancient East possibly are not so widely known, outside the circle of specialists, as they deserve. In his report on the results of the past season (*The Times*, August 1), Dr. Frankfort mentions a number of finds of exceptional interest. As is generally known, one of the objects to which he has given special attention at Tell Asmar and on the neighbouring site of Khafaje is the problem of the early relations of Mesopotamia with both the Indus Valley and the Mediterranean. On both these questions he is able to record new and important evidence, in the former instance pointing to a more intimate relation than the purely commercial connexion, which is all that it has been possible to infer from previous finds. In a temple on a new site, Tell Agrab, the expedition has found among a quantity of interesting material some remarkable examples of stone vases with surprising sculptures. Among these is one fragment which shows the sculptured figure of a humped bull standing before a manger and enclosed in the poles of arches which support a roof. Not only is this a common motif at Mohenjo-daro, but also it belongs to a cult as alien to Mesopotamia as is the humped bull itself. Its occurrence at Tell Agrab should point to a more than casual or commercial contact. Similarly a further link with the Mediterranean is afforded by a terra cotta relief from a small shrine at Tell Asmar, in which one of the figures, possessing one eye only, and associated with fire, is identified as a cyclops. It is interesting to note how many of the interesting series of finds recorded this year by Dr. Frankfort, such as the bowls which had contained a live snake, are to be referred to cults, popular or otherwise, upon which at present we have no information.

Systematists and Text-Books

IN a recent issue of the *Nederlandsch Tijdschrift voor Geneeskunde* (80, 15, pp. 1675–1677; 1936), Dr. L. D. Brongersma directs attention to the deplorable results which can arise through a lack of understanding of the principles of systematic zoology and zoological nomenclature. As an example of his thesis, Dr. Brongersma surveys the most recent edition of a standard text-book of vertebrate comparative anatomy. The confusion to the student which must arise through different authors using different names for the same animal can scarcely be avoided until the systematists have set their house in order, but there can be no possible excuse for the use of two or more names for the same creature within a single chapter; yet that has happened on numerous occasions. Perhaps even more inexcusable are errors arising from the careless confounding of similar names of very different animals. Dr. Brongersma finds that *Hemidactylus* (a gecko) appears amongst the Urodeles, due to confusion with *Hemidactylium*, and *Neomeris* (intended for a porpoise, but strictly applicable to a polyzoan) is confused with a tortoise and is discussed as a reptile! Further difficulties are due to faulty transcription and proof-reading, which have produced a crop of apparently new names, such as *Chelonia speciosa* written instead of *Chelonia sp.* and *Gecko vertis* intended as an abbreviation of *Gecko verticillatus*. The evils attendant on nomenclatorial changes can certainly be minimized by closer co-operation between teachers of zoology and systematists and by a better understanding of the difficulties which confront the latter in the search for stability. It is consequently gratifying to learn that, as a result of Dr. Brongersma's article, a list of corrigenda will be published in the next volume of the particular work he has criticized, and this will itself be submitted to competent systematists before publication.

A Fire in the Mersey Tunnel

SOME of those who have driven through the three miles long Mersey Tunnel may have thought that it was unnecessary to place fire alarms at distances of fifty yards apart throughout the tunnel and to take the many other special precautions against fire which are described in guide books. Remembering that it cost eight million pounds to build and that 5,000 vehicles per hour use the tunnel, it was necessary to take every precaution. The first test of the fire alarm installation occurred on July 25, when a lorry carrying cinematograph films from Liverpool to Birkenhead burst into flames inside the tunnel. The driver at once gave the alarm from one of the fire-alarm boxes, and in less than five minutes the Liverpool and Birkenhead fire brigades had put out the fire. An alarm given at any one of the ninety-eight special boxes is received at both the brigade headquarters. At the same time, large neon 'stop' signs on the roof close the tunnel to traffic, and the pay boxes at each entrance are warned by bells and red lights. The 'electromatic' vehicle-actuated traffic signals are automatically interlocked and allow vehicles to leave and prevent them from entering the affected portions of the tunnel. The alarm is also given to the ventilation control room, from which the large electric air fans can be regulated to meet requirements of any situation that may arise.

The Economics of Railway Electrification

THE *Engineer* of July 17, 24 and 31 contains three short articles on main-line electrification abroad, which are devoted to a statistical survey of the financial aspect of electrification. That electric traction has great advantages for suburban traffic and where water-power is plentiful and coal dear is generally admitted, but the fact that only 2¼ per cent of the total railway mileage in the world is electrified will, perhaps, come as a surprise to those who advocate the adoption of electrification on a wide scale in Great Britain. Of all European countries, in only one, Switzerland, does electrified mileage predominate, and in only six out of twenty does it exceed trifling proportions. Commenting on this, the *Engineer* says: "It is impossible to believe that this neglect of electrification is due to the supineness and conservatism of so many nations. When it is observed that the German national railway system is only electrified to less than 4 per cent, those who are firmly convinced that there is no more technically progressive nation in the universe will have to admit that the arguments against electrical operation must have been overpowering." Electric traction is undoubtedly an extremely efficient means of transport, but against this has to be put the very high capital costs involved. The arguments against electrification have also been strengthened by the great improvements recently made in steam locomotives and the introduction of Diesel-electric units.

German Road Progress

ALTHOUGH it is only two years since Munich entertained the seventh International Road Congress, the city is holding another road congress and in addition a large exhibition of road building machinery on September 16–27. The Research Department of the German State Highways Commission and the leading road construction firms are in charge of all the arrangements. In *Roads and Road Construction* of August 1, Dr. Otto Reismann outlines the programme for the Congress. He points out that the present road construction programme in Germany is on so large a scale, and has been pushed forward so rapidly that great improvements in technical matters have ensued in connexion with road and bridge construction. At the Congress these will be discussed by Government, scientific and industrial experts. The road building machinery exhibition will be held in the open on the Munich Fair Ground, and will show the visitors the very rapid progress made in the mechanization of road construction. The quality of the materials used and the design of the machines have been vastly improved. The Congress will not be confined to purely business sessions. The German motor roads are not built merely for transport purposes. An attempt has been made to build them in such a way that they are in harmony with the landscape and the country in which they lie. Included therefore in the Congress programme are excursions and journeys of inspection over specially constructed motor roads and over the German Alpine highways. At the same time as the Congress there will be an art exhibition on roads as seen by modern art. This is an attempt to demonstrate the strong impression modern art has received from the inspiration of the new roads. It is anticipated that the first 600 miles of the new motor roads (*autobahn*) will be thrown open to traffic in the coming autumn. In two years time, thoroughfares will be completed between Hamburg and Karlsruhe, Stettin and Munich, Ruhr and Karlsruhe, and Stuttgart to Salzburg via Munich.

Crops and Livestock in England and Wales

THE Ministry of Agriculture and Fisheries has recently issued the first part of its publication, "Agricultural Statistics, 1934", entitled "Acreage and Production of Crops and Number of Livestock in England and Wales" (London: H.M. Stationery Office, 1*s*. 6*d*. net), a report which summarizes the annual returns from all holdings exceeding one acre. An outstanding feature is the arrest of the continuous change from arable to grass that has been going on since the Great War, the area under permanent grass showing a reduction on the previous year, whereas the total area under corn has expanded during the same period. As regards roots, the acreage under sugar beet reached a new record figure; that under fodder roots and potatoes, on the other hand, showed a decline. Yields were generally high, being above the average for all corn crops, potatoes, mangolds, hops and several kinds of fruit, though appreciably below normal for hay, turnips and swedes. The numbers of cattle, dairy cows, pigs and poultry have risen since 1933, whereas those for sheep and horses have declined, and as might be expected the output of meat and livestock products, eggs and milk have all shown considerable increases, while the wool clip was substantially reduced. An interesting feature of the report lies in the attainment of many record figures, the yield of wheat and apples being attributable no doubt to the favourable season, and the output of dairy and poultry products to the increase in numbers of cows and birds maintained. Records in area, total production and yield per acre were also reached in the case of sugar beet, while the area under oats, turnips and swedes fell to the lowest figure yet attained, reflecting the changes that are taking place in farming practice.

Mining and Fuel Research at Sheffield

WE have received from the University of Sheffield a report on the research work done in the Departments of Mining and Fuel Technology during the year 1934–35. The former includes numerous subjects, such as mine ventilation, mine lighting, research on trailing cables, accuracy of mine surveys (in which we miss, however, any reference to the very valuable work done by the Institution of Mine Surveyors), subsidence resulting from mining operations, gas testing, movement of firedamp, fireproofing of mine timber, whilst in the Department of Fuel Technology the composition and decomposition and analysis of coal have been carefully studied. The formation of coke, the combustion of coke and the testing of coke have also received attention. A perusal of this pamphlet cannot fail to be of interest to colliery managers.

Symbols for Heat and Thermodynamics

AN attempt will be made to relieve the present chaotic situation with regard to symbols for equations in thermodynamics at an international conference which has been called by the American Society of Mechanical Engineers, to be held in New York on September 14–15, 1936. The Conference has been arranged for this time so that some of the delegates to the World Power Conference to be held the week previous in Washington, D.C., may also act as representatives at the Symbols Conference. American usage in regard to such symbols has become fairly well standardized; but other lists have been issued by various European bodies. The Conference will endeavour to compromise the differences in the several lists.

Fifty Years of West Ham

THE jubilee of the incorporation of the borough of West Ham has been the occasion for the publication of a volume illustrated by maps, photographs and old prints on the history and past and present activities of the borough ("Fifty Years a Borough". Edited by D. McDougall. West Ham County Borough Council 1936). The chief scientific interest in this municipal enterprise is the full account of the growth of the borough from Anglo-Saxon times and its relationship to the Lea and other rivers which were important influences in deciding direction of growth. The chapters on the local government and social services are also of considerable interest.

Sterilization Operations in the United States

ACCORDING to a Science Service bulletin, steady increase in sterilization operations performed on insane and feeble-minded patients in the United States is reported by the Human Betterment Foundation, Pasadena. A total of 23,092 such operations had been officially performed up to January 1, 1936. This does not include operations of this nature privately performed, but is limited to those performed under State laws in the institutions of the twenty-eight States now having sterilization laws in force.

Announcements

PROF. J. BASIL BUXTON, professor of animal pathology in the University of Cambridge, and director of the Institute of Animal Pathology and of the University Field Laboratories, Cambridge, has been appointed acting principal and acting dean of the Royal Veterinary College from September 25, and to succeed Sir Frederick Hobday as principal and dean on the retirement of Sir Frederick after the opening of the main block of the new college buildings.

AT a recent meeting of the North East Coast Institution of Engineers and Shipbuilders the following awards were made: *Institution Gold Medals* (Engineering), to Eng. Comdr. C. J. Hawkes and G. F. Hardy, for a paper entitled "Friction of Piston Rings"; (Shipbuilding), to R. C. Thompson, for a paper entitled "Modernizing the Motor Vessels 'Silverpine' and 'Silverlarch' and Increasing Their Service Speed"; *M. C. James Medal*, to W. C. S. Wigley, for a paper entitled, "The Theory of the Bulbous Bow and Its Practical Application"; *Institution Scholarship*, to Anthony Gilchrist; *Thomas Fenwick Reed Medal*, to Dr. Will Pratt.

THE second International Congress of the International Association for Testing Materials will be held in London on April 19–24, 1937, under the presidency of Sir William Bragg. The Congress will be open to anyone on payment of membership fee. The subjects selected for discussion will be classed into the following groups: A, Metals; B, Inorganic Materials; C, Organic Materials; D, Subjects of General Importance. Further information can be obtained from the honorary secretary, Mr. K. Headlam-Morley, 28 Victoria Street, London, S.W.1.

DR. MAX BODENSTEIN, professor of physical chemistry at Berlin, has been awarded the Bunsen Medal by the German Bunsen Society for applied physical chemistry, and Dr. Max Le Blanc, professor of physical chemistry at Leipzig, has been elected an honorary member of the Society.

DR. DONALD D. VAN SLYKE, a member of the Rockefeller Institute of Medical Research, has been awarded the Charles Mickle fellowship of the University of Toronto for his work on blood analysis, respiratory and renal reactions, diabetes and nephritis.

A MINISTRY of Health has recently been formed in Belgium under the direction of M. Emil Vandervelde, the well-known Socialist leader.

THE twenty-fifth Congress of the German Physiological Society will be held at Giessen and Bad Nauheim on August 30–September 2 in conjunction with the German Pharmacological Society. Further information can be obtained from Prof. Dr. Burker, Physiologisches Institut, Giessen.

THE twenty-third French Congress of Hygiene will be held at the Institut Pasteur, Paris, on October 20–22, under the presidency of Prof. Leclainche. Further information can be obtained from the general secretary, Dr. R. Dujarric de la Rivière, Institut Pasteur, 28 rue du Docteur Roux, Paris, 15^e.

FOUR committees (medical, engineering, economic and legal, and administrative) have been appointed in the United States, consisting of health experts, representatives of employers, workers, insurance companies, Government, technical societies and engineers, to attempt to devise a method for putting an end to silicosis.

EIGHTY-SIX cities in the United States with an estimated population of 37 millions reported 8,799 deaths from motor accidents in 1935 as compared with 9,060 deaths in 1934. Forty-eight of the cities showed a decrease in the total number of fatalities; thirty-six showed increases and two cities reported the same number of deaths in 1935 as in 1934.

THE fifteenth Annual Clinical and Scientific Session of the American Congress of Physical Therapy will be held at the Waldorf-Astoria Hotel, New York, on September 7–11. The programme will include symposia on short-wave diathermy, hydrotherapy, exercise, electro-resection, fever therapy, treatment of vascular diseases, the educational aspects of physical therapy, the relationship of physical technicians to physicians and hospital departments, and technical and scientific exhibits. Further information can be obtained from Dr. Norman E. Titus, 730 Fifth Avenue, New York.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

Two assistant experimental officers (Grade *D*) (physics or engineering) in a War Department at Woolwich—The Superintendent, Experimental Signals Establishment, Woolwich Common, S.E.18 (August 18).

A scientific officer (physics or engineering) in a Government establishment of the War Department—The Secretary, Royal Engineer Board, Regent's Park Barracks, Albany Street, N.W.1 (August 26).

A chemist in the Department of War Department Chemist—The Under-Secretary of State (C.5), War Office, S.W.1 (September 7).

An assistant keeper in the Science Museum, South Kensington, S.W.7—The Director (September 7).

An Elder professor of anatomy and histology in the University of Adelaide—The Secretary, Universities Bureau of the British Empire, 88a Gower Street, W.C.1 (September 20).

A temporary lecturer in zoology in the University of Cape Town—Prof. T. A. Stephenson (October 5).

A lecturer in civil engineering and building in the Portsmouth Municipal College—The Registrar.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 292.

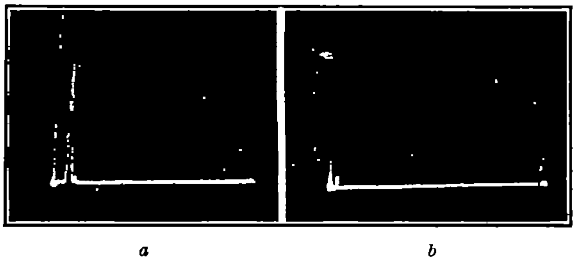
CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Some Observations on the *C* Regions of the Ionosphere

RECENT observations at Calcutta[1,2], at Morgantown (U.S.A.)[3] and Orfordness (England)[4] have established beyond doubt the existence of ionized layers much below the Kennelly-Heaviside *E* layer. Not infrequently these layers act as good reflectors of radio waves. The topmost of these layers (sometimes called the *D* layer) is situated at an average equivalent height of 55 km. The next one lies between 20 km. and 35 km., and the lowest ones appear to be situated within the tropospheric region between heights of 5 km. and 15 km. (It has recently been suggested by Mitra[5] that since the designation *D* is usually applied to the non-deviating absorbing 'tail' of the *E* region, the new regions be called *C* regions. It would perhaps be convenient to call them, starting from the top, C_1, C_2, and C_3 regions.)

Since data regarding the properties of these regions —particularly of the lower ones—are still lacking, we have recently carried out a series of 24-hour observations, at intervals of one hour and a half, using a frequency range of 1–15 mc./sec. The results of our observations are summarized below.

(1) Echoes from C_1 (55 km.) are much more frequent and are of greater strength than those from C_2 and C_3. C_2-echoes (25–30 km.) are also strong and are more frequent than C_3-echoes; the latter are weak and are observed on rare occasions. C_1, *E*- and *F*-echoes of moderate strength have been observed on several occasions to occur side by side.



a *b*

FIG. 1. Echoes from. (*a*), C_1 region (55 km), (*b*), C_2 region (20 km.).

(2) Echoes recorded during day-time are invariably weaker than those recorded during the night. The intensities of C_1- and C_2-echoes have occasionally been found at night to be comparable with those of fairly strong *E*- and *F*-echoes.

Fig. 1*a* shows a C_1-echo (55 km.) with 3 mc./sec. frequency as received at midnight of June 5. Fig. 1*b* shows a C_2-echo (20 km.) with a frequency of 2·18 mc./sec. recorded at 1900 hours on June 12. A closer examination will reveal the presence in Fig. 1*b* of another very low height echo (8 km.) and traces of single and double reflections from the *E* region.

(3) Echoes have been observed at all times of the day and night; but they seem to be more frequent during the afternoon and are usually too weak to be detected at about midday.

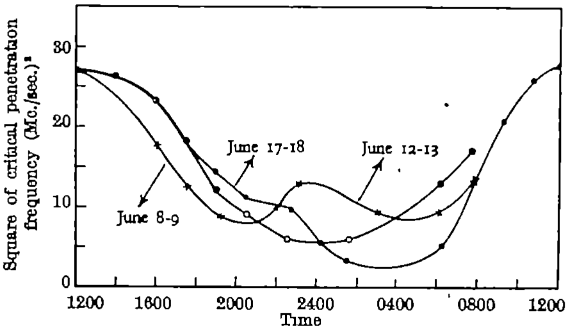


FIG. 2. Hourly variation of the square of the critical penetration frequency (noon to noon) of the C_1 region (55 km.) on three typical days.

(4) Curves in Fig. 2 represent hourly variation of the square of the penetration frequency (f^2) for the C_1 region for three selected days and are typical of those usually obtained in the course of our observations. It is evident that the ionization in general attains its daily maximum at about noon, and tends to a minimum during the small hours of the morning. There are also at times abnormal variations which appear to be more pronounced at night. The general nature of the hourly variation, however, leads one to conclude that the ionization is of solar origin.

(5) The critical penetration frequencies of the C_2 and C_3 regions have been obtained occasionally. But the occurrence of these echoes, particularly those from C_3, is not frequent enough to enable one to study the hourly variation of ionization of the corresponding regions. It may, however, be mentioned that the average values of the penetration frequencies are of the same order as those for the C_1 region.

The observations described here were carried out at the suggestion of Prof. S. K. Mitra.

H. RAKSHIT.

IN connexion with the above observations of Dr. Rakshit and Mr. Bhar on the *C* regions, I would like to point out that it is not justifiable to take the hourly variation of f^2 as proportional to the variation of the ionization density (N) in these low regions of the ionosphere. The collisional frequency (ν) is high at such levels, and in the C_1 region it is perhaps comparable with $2\pi f$. Conditions favourable for reflection (or penetration) may be brought about either by an increase (or decrease) of N or by a decrease (or increase) of ν. It is quite conceivable that the atmospheric density and, along with it, ν, varies from hour to hour at such levels, and the abnormalities observed in Fig. 2 may have been caused either by a variation of N or by a variation of ν or by both occurring simultaneously.

Existence of a Surface Wave in Radio Propagation

IN the mathematical development of the problem of radio propagation over plane earth, Sommerfeld[1] expressed his solution in the form of three terms, one of which he identified with the surface wave of Zenneck[2]. Curves calculated from Sommerfeld's formula have been given by Rolf[3]. Weyl[4], approaching the problem in a different manner, obtained a solution which did not explicitly contain this term. A formula given by Norton[5] gives values agreeing with Weyl. It appears that Weyl was of the opinion that his result was numerically equivalent to that of Sommerfeld. The purpose of this letter is to point out that this is not true, that the evaluation of Sommerfeld's formula by Rolf differs from the formulæ of Weyl and Norton by exactly the 'surface wave' component, and to give the results of a recent experiment showing the Weyl–Norton values to be the correct ones, which raises a question as to whether surface waves do or do not physically exist.

Previously available experimental data that might be used to decide which expression is correct have, unfortunately, been obtained under conditions for which Sommerfeld and Weyl do not differ greatly. For ultra-short wave propagation over deep fresh-water, however, their results differ enormously. To make a test under these crucial conditions, an experiment on the propagation of 2-metre waves has been conducted over Seneca Lake, New York State. The variation of the field with distance was found to agree well with Weyl. At a distance of about 1·8 km., where Sommerfeld's formula gives values about 1,000 times that of Weyl, the field was studied as a function of antenna height and polarization. Whereas Sommerfeld's expression for the surface wave gives values decreasing with height, the measured field actually increased. At the greater heights, the field was independent of polarization, as it should be if there were no surface wave. Since there is no uncertainty in the correct formula to use for horizontal polarization, this comparison showed that the field at the earth's surface was about 0·001 of the value predicted by Sommerfeld. It seems evident that a revision of the Sommerfeld–Rolf curves is required for propagation over all types of ground for which the dielectric constant cannot be neglected.

Specific Ionization of Cosmic Radiation

AFTER Danforth and Ramsay's recent publication[1] I think it would be of interest to give here briefly the results of similar work, carried out last year, the conclusions of which have been proposed as a thesis at the University of Brussels (April 29, 1936) but cannot be published *in extenso* in a periodical before December next.

The problem is to measure the specific ionization of a penetrating radiation (cosmic radiation, fast electrons, etc.) by the comparison of the efficiency of a Geiger-Muller counter (single impulse or coincidence) corresponding to different internal pressures.

This method was indicated by Tuwim[2] in 1931, and by us[3] in 1933. The integration necessary for the determination of the mean length of the internal path was resolved by Tuwim and Kolhorster[4] (1933) in a particular case; unfortunately, that case was not very convenient for the precise determination of specific ionization.

I have solved that integration graphically and numerically with sufficient approximation (error less than one per cent) in the general case of two identical counters, parallel, connected for counting coincidences.

This calculation shows that the approximate formula used by Danforth and Ramsay, and by me in 1933, was definitely different from the true one (more than five per cent discrepancy). I had also shown experimentally that a single pair of ions gives a discharge of the counter with a probability of 0·999; the corrections due to showers, accidental coincidences, recovery time, latent time, barometric effect, etc., have been discussed and taken into account.

The counters used had an over-voltage range of the order of 1,000 volts, a reproducibility better than 0·5 per cent during many months, and a residual frequency of impulses that may be neglected.

The following results were found: Total cosmic radiation:

Specific primary ionization:	
Hydrogen	5·96 ± 0·07 cm.$^{-1}$ (0°–760 mm.)
Helium	5·96 ± 0·15 ,,
Argon	29·40 ± 2·0 ,,
Specific total ionization:	
Argon	71·40 ± 2·0 ,,

Absolute intensity of cosmic radiation (number of rays crossing per second a sphere of 1 cm.^{2} of cross-section):

Brussels (reduced to sea-level) (760 mm.):

$$0{\cdot}0266 \pm 0{\cdot}0003 \text{ cm.}^{-2} \text{ sec.}^{-1}.$$

The concordance between the experimental results and the calculated curve (mean error, 0·9 per cent, equal to the calculated most probable error due to uncertainty of readings) indicates a remarkable homogeneity of specific ionization of the different components of cosmic radiation (primary and secondary).

Diffraction of Light by Ultra-Sonic Waves

IN a recent paper, R. Lucas[1] has described an experiment designed to test the relative merits of a theory, proposed by C. V. Raman and N. S. Nagendra Nath, of the scattering of light by high-frequency sound waves and that due to himself and P. Biquard. The two theories differ in that, while Raman and Nath assume only a change in phase of normally incident light as it progresses through the sound field, Lucas and Biquard's theory takes account of changes in both amplitude and phase. Lucas's experiment appears to prove by indirect methods that the theory of Raman and Nath is true only for sound fields of thicknesses of the order of 4 mm. or less. R. Bär[2] has also reported on an experiment which indicates that while the Raman-Nath theory predicts a type of intensity distribution which agrees qualitatively with the observed patterns at frequencies of 1·5 and 7·5 megacycles, there are several discrepancies which indicate that the fundamental assumption of these authors is incorrect. The portion of their theory dealing with oblique incidence apparently gives results which are not in accord with the observations, particularly at the higher frequency. Furthermore, Bar has obtained 'photographs' of the actual ultra-sonic grating by the insertion of a photographic plate in an appropriate position in the light beam behind the stationary sound field. With no lens system of any type to focus the light rays, a series of quite sharp fringes appears on the plate, indicating the presence of some changes in light amplitude as well as in phase.

I have recently completed some experiments, which are to be published shortly in the *Canadian Journal of Research*, in which the distribution of light energy among the various diffraction orders has been measured as a function of ultra-sonic intensity at a number of frequencies in the region of 5 megacycles per second. Using light of wave-length 589 mμ, path lengths of about 2·5 cm. and ultra-sonic intensities ranging from zero to about 0·2 watts per cm.^{2}, it is found that the envelopes of the diffraction patterns as predicted by the Raman–Nath theory are in excellent agreement with the observations for light scattered in both progressive and standing wave fields, the intensities of positive and negative orders from zero to five being measured.

In view of this close agreement, it appears somewhat strange that further experimental evidence should indicate the fundamental assumption of Raman and Nath to be in error. The explanation may possibly be found in the deviations of a practical sound field from the ideal case postulated by these authors, who for simplicity assume the sound field to consist of a rectangular prism of plane waves, the sound intensity over any plane normal to the direction of motion of the waves being constant at any instant. A light ray incident normally on such a field would suffer retardations in phase only. In the practical case, however, the sound field does not fulfil these conditions, particularly at the edges. It is probable that a light ray incident in a direction normal to the axis of the field may suffer some refraction on entering the sound field. Once bent, the ray will be traversing layers of varying refractive index and will suffer some changes in amplitude. Eventually, the various rays may come to a series of foci, thus producing the fringes observed by Bär. In such a field the Raman–Nath theory for oblique incidence might also fail, as noted by Bär.

The fact that the discrepancies between theory and observation are less at the lower frequencies tends to support the above hypothesis since, as the sound wave-length is increased, the probability of a light ray entering the field under the conditions postulated by Raman and Nath is considerably greater. In the case of normal incidence, it is quite conceivable that small changes in amplitude, coupled with the normal changes in phase, give rise to an emergent light wave surface which approximates very closely to that which would be produced if changes in phase alone had occurred. That this is the case appears to be substantiated by the very close agreement between the predicted intensities in the various orders and those measured quantitatively by me and observed qualitatively by Bär.

Until a theory is developed which takes complete account of the nature of a practical sound field, it would hence appear that the theory of Raman and Nath, though based on an assumption which is somewhat erroneous in the practical case, describes most accurately the nature of the diffraction effects observed.

Absorption Spectrum of Heavy Methane (CH$_3$D) in the Photographic Infra-Red

WE have recently prepared 40 litres of mono-deuteromethane and examined its absorption spectrum in the photographic infra-red from 12,000 A. to 6000 A. under the high dispersion of a grating spectrograph. Examination of our plates reveals complete absence of even the strongest lines of ordinary methane ; absence of the heavier methanes was shown by density determinations carried out on a specially fractionated sample.

The spectrum includes a region of intense absorption extending from 8350 cm.$^{-1}$ to 9000 cm.$^{-1}$ with a particularly strong and broad maximum at 8617 cm.$^{-1}$. The structure here is complex, but if anything simpler than with ordinary methane, although no obvious regularities stand out. Of particular interest is the occurrence at 9065 cm.$^{-1}$ of a band with a simple structure of regularly spaced lines (approximate spacing 7·5 cm.$^{-1}$) and with what may be a Q branch at 9021 cm.$^{-1}$. In the case of methane[1], a similar band is found at 9047 cm.$^{-1}$ with a spacing of 10·5 cm.$^{-1}$, and apparently similar bands are also shown by methyl halides[2] round about 9025 cm.$^{-1}$. The region from 9600 cm.$^{-1}$ to 10,200 cm.$^{-1}$ is occupied by some ten fainter bands. Then from 10,960 cm.$^{-1}$ to 11,220 cm.$^{-1}$ come four bands, that at 11,220 cm.$^{-1}$ being relatively strong and very similar in appearance to the methane band of the same frequency.

A detailed discussion of this spectrum will shortly be published elsewhere.

The Cepheid Variables and Black-Body Radiation

IN dealing with the problem of determining the concurrent variations in radius and temperature in the Cepheid variables, in order, for example, to construct the Milne diagram[1] for the variability, two possible alternative points of view may be considered, each being inconsistent with the other.

(1) The radial velocities, determined from the displacement of the absorption lines in the spectrum, can be taken to represent unchanged the radial motion of the photosphere. In this case the pulsation theory in its present form has to be abandoned, and it is further necessary to assume that the Cepheid radiation deviates very markedly from that of a black body. These are the postulates favoured by Getting[2], who has in this way prepared Milne diagrams for a number of Cepheids.

(2) We may assume the radiation to approximate closely to that of a black body, and consider the radial velocities to give a measure of the motion of the atmospheric layers only. The radius of the photosphere at any phase must then be considered as completely unknown; the temperature and radius can, however, be determined by the application of the Planck radiation formula, from magnitude determinations in light of two different wave-lengths.

At the present stage of our knowledge, it appears doubtful, however, whether we can assume, a priori, that the velocity of the atmospheric layers reflects the motion of the photosphere. It is known that the radial velocity curve differs for lines at different levels in the atmosphere, both with regard to phase and to amplitude. It is difficult to decide which level is to be taken as representing the motion of the photosphere.

Further, we are at present unable to give a satisfactory picture of the chromosphere in a static star. It follows therefore that the problem of the pulsations of an extended atmosphere in which the photospheric temperature and surface gravity are both undergoing considerable variations is very far from solution; in fact, until some attempt has been made to predict the behaviour of such an atmosphere, it appears advisable not to use the radial velocities to determine the motion of the stellar body.

If (1) fails, we are forced to investigate the possibility that the Cepheids radiate as black bodies. A recent investigation by Kox[3], with this object, has led to the conclusion that this is definitely not the case. Kox has, however, made the initial assumption that the radial velocities give the stellar motion, which is inconsistent with the possibility of black-body radiation, so that his conclusion is not unexpected, and must be regarded as invalid. If, in conformity with (2) above, we assume the radius at any phase to be completely unknown, Kox's observations of the amplitude of light variation in two regions of different wave-length enable us to calculate maximum and minimum temperatures and radii, but are incapable of providing a test of the agreement of the stellar radiation with that demanded by the Planck formula.

It is obvious, however, that if the amplitude of light variation could be determined in three or more wave-lengths, the maximum and minimum temperatures and radii could be calculated from the results of any two such determinations. If the Planck formula is satisfied, the remaining observations should all be consistent with these results.

Kox gives material for δ Cephei from other investigations which enable us to test this conclusion. It is found that if all observed amplitudes are corrected by the same term, depending on the maximum and minimum radii, determined from two observations, the temperature range ΔT required to produce the corrected variation in light is 1,810°. The probable error of a single ΔT is 30°, which would be produced by an error of approximately 0·015 mag. in the observed amplitude, and can, therefore, be explained entirely by errors of observation.

On the present data, the conclusion therefore is that the light variation in the Cepheids is consistent with the joint assumptions:

(*a*) The stars radiate to a close approximation as black bodies.

(*b*) The photospheric radius is considerably greater at minimum light than at maximum, that is, the radial velocities are not to be regarded as reflecting unchanged the motion of the photosphere.

Thermal Conductivity of Deuterium

IN the course of an experimental investigation of thermal conduction in deuterium-hydrogen mixtures, recently completed, determinations of the absolute value of the thermal conductivity of deuterium have been made. The method used in these determinations was the hot wire method as developed by Gregory and Archer[1,2].

The deuterium was prepared from deuterium oxide of guaranteed 99·95 per cent concentration, supplied by Imperial Chemical Industries, Ltd., and two independent methods of preparation were adopted:

(1) The vapour of the deuterium oxide was passed over pure magnesium, heated by means of an electric furnace to about 500° C. in a quartz tube, after very careful and prolonged de-gassing of the magnesium. In this instance, the value of the thermal conductivity of deuterium at 0° C. obtained from the measurements was

$$0{\cdot}000308_2 \text{ cal. cm.}^{-1}\text{ sec.}^{-1}\text{ deg.}^{-1}\text{ C.}$$

(2) The deuterium was prepared by decomposition of the oxide by metallic sodium, the sodium having been previously boiled *in vacuo* to remove all traces of air and other impurities. In this case, the value of the thermal conductivity of deuterium at 0° C. found was

$$0{\cdot}000307_8 \text{ cal. cm.}^{-1}\text{ sec.}^{-1}\text{ deg.}^{-1}\text{ C.}$$

In both cases, the observations were checked by repetition of the preparations, using different samples of the deuterium oxide. Also, the same apparatus was used to determine the thermal conductivity of pure hydrogen, prepared by the magnesium method from pure water. The value at 0° C. was found to be

$$0{\cdot}000418_2 \text{ cal. cm.}^{-1}\text{ sec.}^{-1}\text{ deg.}^{-1}\text{ C.}$$

The accuracy of all the results is estimated to be of the order of 0·25 per cent.

It is of interest to note that the value for deuterium obtained by calculation[3] from the experimental value for hydrogen is

$$0{\cdot}000295_7 \text{ cal. cm.}^{-1}\text{ sec.}^{-1}\text{ deg.}^{-1}\text{ C.,}$$

while the actual measurements of Kannuluik[4] gave

$$0{\cdot}000329_4 \text{ cal. cm.}^{-1} \text{ sec.}^{-1} \text{ deg.}^{-1} \text{ C.}$$

A detailed account of the investigations will be published elsewhere in the near future.

Effects of Hypertonic Media on the Contractile Vacuoles of Protozoa

IT has long been suspected that the contractile vacuoles of Protozoa maintain the internal osmotic pressure of the organism above that of the external medium, and it has been argued that, if this is correct, the rate of vacuolar output should be reduced when the external osmotic pressure is raised. This has been found to be true for various Ciliata, and recent work has made it necessary to examine evidence of this nature more critically.

In Peritrich Ciliates[1] and in *Paramecium*[2], it has been found that if the external osmotic pressure is raised sufficiently the body shrinks, but that the contractile vacuole may continue to eject water, although at a reduced rate, even after this shrinkage. Kamada[2] has argued from his results with *Paramecium* that since the body has shrunk, the internal osmotic pressure is no longer above the external osmotic pressure, and hence that no more water can be entering through the body surface, and therefore in turn that the water ejected by the contractile vacuole must be of internal and metabolic origin. This argument is open to criticism.

According to the osmotic control theory, the contractile vacuole acts as a pump which, by utilizing energy, ejects water and retains the salts of the organism. There is no reason whatsoever why the contractile vacuole should stop as soon as the external osmotic pressure is raised so as to equal or exceed the (original) internal osmotic pressure of the organism. Its continuance would lead to a raising of the internal osmotic pressure by a shrinkage of the body until a new and steady value was attained above that of the new external medium. One might, however, expect a decrease in rate of output owing to the increased energy required to separate water from a more concentrated internal solution. Only if the external osmotic pressure were raised very considerably above the original internal osmotic pressure of the organism would one necessarily expect the contractile vacuole to stop completely.

After an increase in the osmotic pressure of the external medium, in the process of reaching a new steady state (1) the body will shrink, and the internal osmotic pressure will therefore be raised, with the result that (2) the rate of vacuolar output will (probably) decrease, and (3) the rate of entry of water by osmosis through the body surface will increase (even from zero or from a negative value). The body volume will become constant when it has decreased to such a value that the rates of loss (2) and gain (3) of water are equal. There is no reason for expecting a linear relationship between rate of vacuolar output and external osmotic pressure. The rate of vacuolar output will be dependent on unknown internal factors such as the water content or salt concentration of the tissues. This theory is in good accordance with the data which are available for Ciliata.

The situation is more complicated for *Amœba*, and the evidence is more conflicting, although a similar explanation may be applicable. Adolph[3] found that the contractile vacuole of *Amœba proteus* maintained its rate of output undiminished when the organism was subjected to pure solutions of sodium chloride or other salts up to $M/20$ in concentration (that is, of osmotic pressure equal to about one-tenth of that of sea water). But Zuelzer[4] found that fresh-water amœbæ lost their contractile vacuoles when transferred to sea water, and Hogue[5] found that marine amœbæ developed contractile vacuoles when cultured on an agar medium made up with fresh-water.

It seems therefore probable that Adolph did not use strong enough solutions, and in any event pure sodium chloride is scarcely a suitable medium for the purpose. It may be stated in conclusion that the situation as regards amœbæ is still unsettled, but that the evidence so far available is not inconsistent with the osmotic control theory of the contractile vacuole.

Colloid Osmotic Pressure of the Body Fluids of Freshwater Animals

THE fact that the colloid osmotic pressures exerted by the body fluids of marine animals arrange themselves in the order of their phylogenetic development[1], suggested that there exists a definite relationship between the general organization of an animal and the colloid osmotic pressure of its body fluids. The results of the measurements undertaken with the hæmolymphs of some terrestrial invertebrates confirmed this hypothesis; the values obtained[2] were indeed practically the same as those of the body fluids of the corresponding marine animals. I concluded from these observations that neither sea water nor air as surrounding media have any marked influence on the above-mentioned relation.

It was interesting to see whether this relationship is modified by life in fresh-water. I have therefore measured the colloid osmotic pressures of the body fluids of some freshwater animals and compared the results with the data previously found for the corresponding marine groups. The animals used were one species of lamellibranch Molluscs (*Anodonta cellensis*), two species of gasteropod Molluscs (*Limnœa stagnalis*, *L. auricularis*), one decapod Crustacean (*Astacus fluviatilis*), and three teleostean fishes[3] (*Cyprinus carpio*, *Esox lussius*, *Anguilla vulgaris*). The following table gives the average values of each of these groups (except the values obtained with the serum of the eel, which will be discussed below) and, for comparison, the average values of the corresponding marine animals :

	Marine animals (cm. H_2O)	Freshwater animals (cm. H_2O)
Lamellibranch molluscs	1·1	0·8
Gasteropod molluscs	1·5	1·2
Decapod crustaceans	3·6	3·1
Teleostean fishes	19·0	11·9

The table shows that the colloid osmotic pressures of the body fluids of freshwater animals arrange themselves, as well as those of the marine animals, in the order of phylogenetic development. The parallelism between the two series of figures is striking. There is, however, a marked difference between the marine animals and those living in fresh-water: the values for the freshwater animals are 20–35 per cent lower than those given by the body fluids of the marine animals. This difference does not conflict with the hypothesis of a relation between the general organization of an animal and the colloid osmotic pressure of its body fluids, but even strengthens it. The freshwater fauna being considered as a regressive branch of the aquatic fauna in general, this regression expresses itself by a diminution of the colloid osmotic pressure of the body fluids of these animals.

There is one exception from this rule: the eel's serum exerts a colloid osmotic pressure varying from 19·9 to 27·2 cm. H_2O. This exception, however, does not in the least weaken the hypothesis; though passing a great part of its life in fresh-water, the eel must essentially be considered as a marine fish. The colloid osmotic pressure of its serum has indeed the same value as that of one of the most active marine Teleosteans, that is, *Labrax lupus*.

[3] A. Keys and R. M. Hill (*J. Exper. Biol.*, 11, 28; 1934) had already measured the colloid osmotic pressure of the serum of three freshwater teleosteans (*Tinca vulgaris*, *Esox lussius* and *Anguilla vulgaris*). The figures reported by these authors agree with the values recorded in this note.

Metabolism of Cartilage

In reply to the letter of Dickens and Weil-Malherbe[1], a previous communication[2] on this subject was based, except where rabbit cartilage was specified, on more than one hundred experiments with cartilage from the carpo-metacarpal joints of the adult horse, to whose metabolism that of human cartilage is very similar.

As regards the rabbit, hyaline cartilage from the femur has an anaerobic glycolysis of 1·0 for the first few hours, falling to an average of 0·6 over the 24 hours: the figures cited previously refer to meniscus (fibrocartilage) over a period of 24 hours in an experiment lasting fourteen days. A comparable figure is that for the first hour, 0·6.

Respiration measurements have not yet been made on rabbit material, but it is perhaps of interest:

(1) That the well vascularized epiphyseal cartilage of the fœtal rabbit has an anaerobic glycolysis ten times as high as the adult, or, per cell, twice as high.

(2) That a human enchondroma showed a glycolysis thirty times that of normal cartilage and an oxygen uptake of 0·34.

Intermediate Metabolism of Carbohydrates

We have found some new chemical reactions in living cells which represent steps in the breakdown of carbohydrates. Pyruvic acid, if added to animal tissues, disappears rapidly not only in the presence, but also in the absence of oxygen. In the presence of oxygen the end-products of the pyruvic acid metabolism are known to be carbon dioxide and water. We find that the primary steps of the oxidation proceed in the absence of molecular oxygen, and as products of the anaerobic oxidation the following substances were identified: (1) acetic acid, (2) carbon dioxide, (3) succinic acid.

The reductive equivalent for the oxidation of pyruvic acid is the conversion of another fraction of pyruvic acid into lactic acid or the homologous reduction of another ketonic acid. The quantitative data suggest that pyruvic acid is metabolized by the following intermolecular oxido-reductions: The first step is a dismutation of pyruvic acid according to the reaction:

(1) 2 pyruvic acid + water → acetic acid + carbon dioxide + lactic acid.

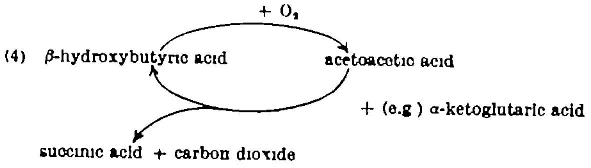
The evidence for the occurrence of this reaction in the tissues which metabolize carbohydrates is conclusive. The subsequent reactions which lead to the formation of succinic acid may be tentatively formulated in the following way:

(2) acetic acid + pyruvic acid + 'ketonic acid' → α-ketoglutaric acid + 'hydroxy acid'.

(3) α-ketoglutaric acid + 'ketonic acid' + water → succinic acid + carbon dioxide + 'hydroxy acid'.

According to (2) α-ketoglutaric acid is formed by the oxidative condensation of pyruvic and acetic acids, a ketonic acid acting as hydrogen acceptor. According to (3), α-ketoglutaric acid is oxidatively decarboxylated by dismutation. Reaction (3) is analogous to (1).

The experiments suggest that different 'ketonic acids', such as pyruvic acid, acetoacetic acid, oxalacetic acid[1], or their homologues may be concerned in reactions (2) and (3), and may possibly take the place of pyruvic acid in (1). It seems that acetoacetic acid reacts preferentially in (3), and it is therefore of great interest that we find in tissues which metabolize carbohydrates a specific system which catalyzes the oxidation of β-hydroxybutyric to acetoacetic acid by molecular oxygen[2]; β-hydroxybutyric acid may thus act as a carrier for molecular oxygen according to the scheme (4).



+ O_2
(4) β-hydroxybutyric acid
acetoacetic acid
+ (e.g.) α-ketoglutaric acid
succinic acid + carbon dioxide

As is indicated in (4), α-ketoglutaric acid is not directly oxidized by molecular oxygen, but through the intermediation of another ketonic acid. It has long been known that there are links between carbohydrate breakdown and 'ketone bodies', and it is now possible to describe this link, or at least one of the links, in chemical terms.

The oxidative formation of succinic acid from pyruvic acid has been discussed by previous workers.

The new feature is the demonstration that this oxidation is brought about by anærobic oxido-reductions. The reactions described seem to occur in all animal tissues which metabolize carbohydrates. They occur also in bacteria. Reaction (1), for example, is quantitatively realized in gonococci.

The work of Peters[3] and the findings of Simola[4] suggest that vitamin B_1 is a co-enzyme for dismutations of the type of the reactions (1) and (3). Experiments on tissues of vitamin B_1 deficient rats and chickens show that such is the case.

Length of Saccharide Chains in Glycogens from Different Sources

EMPLOYING Haworth's 'end-group assay' method, it has already been shown that rabbit liver glycogen formed under normal conditions has a chemical molecule built up of a chain of 12 glucose units[1,2]. Fish (Gadidae) liver glycogen also conforms to this structure[2].

Haworth afterwards recorded that glycogen (source not mentioned) may also exist derived from 18 units[3].

I have now examined, by the above method, the glycogens (*a*) laid down in the liver after oral administration of galactose to fasted rabbits; and (*b*) from the whole tissue of *Mytilus edulis*. In each instance the mean number of glucose units in the chemical molecule of the polysaccharide has been found to be 18.

This fact was revealed only following examination of the cleavage products of the methylated glycogen in question. No apparently significant differences from 12 unit glycogen could be demonstrated by examination of the purified polysaccharides themselves with respect to $[\alpha]_D$, reducing power, rate of hydrolysis, or properties of the acetylated or methylated derivatives.

These investigations will be fully reported through the usual channels.

Inhibitory Effect of Phloridzin and Phloretin on Kidney Phosphatase

THE inhibitory effect of phloridzin on phosphatase action[1] is well pronounced only when rather high concentrations (about *m*/50–*m*/100) of the poison are used. The phloridzin concentrations which are able to prevent any reabsorption of glucose in the kidney are definitely lower[2] (about 0·5–1 mgm. per gm. kidney). Phloridzin is hydrolyzed by *N* hydrochloric acid at 100° into glucose and phloretin.

The present communication shows that the inhibitory effect of phloretin on kidney phosphatase is about three to four times as high as that of phloridzin. In alkali at 100° the phloridzin is hydrolyzed into phloroglucin-glucoside and phloretin acid. Here also an increase in the poisonous action (about twice) is observed. Phloroglucin has no poisonous action on phosphatase; pure phloroglucin-glucoside has not been tested. However, phloroglucin-glucoside inactivates the reabsorption of glucose in the kidney[3].

Exp. 24/6. Kidney phosphatase; veronal buffer *p*H 8·5; temp. 38° C.; incubation, 60 min.

Substrate: glycerophosphate	Ester hydrolysis (mgm. P)	Per cent inhibition
Normal sample	0·350	
Phloridzin *m*/370	0 292	15
Phloretin *m*/370	0 152	57

In this connexion, it is of interest that liver and kidney contain great amounts of β-glycosidases; phloridzin-glycosidase has been found in horse kidney[4].

Steady Performance of Geiger-Müller Counters

DUE to rapid discharges that take place in a counter, a considerable amount of gas may easily be liberated, or in some cases even adsorbed, causing fluctuations of pressures in the counters. After working for some time, the voltage initially found to be suitable may no longer be so, and may lie beyond the limits within which the counts are independent of variations of applied voltage. This is more likely to occur with low-pressure counters than with high-pressure ones, since the working range of voltage diminishes with diminution of pressure. Herein lies the cause of unsteadiness.

One way of remedying this unsteadiness is to increase the pressure in the counter; but this necessitates the use of very high voltages to the counter. Two other ways are open. By the use of suitably high resistances between the counter and the battery, the tendency for a heavy arcing discharge to be initiated by the condenser discharge can be checked. Another way is to use a big reservoir in connexion with the counter volume. The large volume makes changes of pressure negligible.

We have found that counters in which no counting range could be detected easily gave such ranges on the insertion of a ten-litre volume. This arrangement was tested for pressures from 5 mm. up to 10 cm. with counters of different dimensions, air being used in all cases. Tinned copper wire of about 0·3 mm. diameter was used for the central electrode. The tinning was done not for any special reason, it being the usual 5 amp. fuse wire. The material of the outer electrode is brass, in thin sheet and enclosed in a sealed glass tube.

Vibrational Frequencies of Molecules

IN a recent letter to NATURE[1], I submitted evidence that the ground state vibrational frequency of a molecule AB was the mean of the frequencies of the molecules A_2 and B_2 provided that A and B belong to the same group of the Periodic Table. I was then unaware of the work of Dr. C. H. Douglas Clark[2], who had previously arrived at the same conclusion. To account for certain deviations from this rule, he adds the further condition that the frequencies of A_2 and B_2 must not be too dissimilar in magnitude.

If the motion of a diatomic molecule AB be considered simple harmonic, the vibrational frequency ω is given by the expression:

$$\omega = \frac{1}{2\pi}\sqrt{\frac{M_A + M_B}{M_A \cdot M_B}\cdot K},$$

where M_A and M_B are the atomic weights of A and B respectively and K is the force constant. It is reasonable to assume in the first instance that for such molecules as A_2, B_2 and AB, the force constant K will have the same value. A simple calculation then shows that the above relation between the vibrational frequencies follows if the masses M_A and M_B are of the same order. Consequently the frequencies of A_2 and B_2 should also be of the same order, thus accounting for Clark's second condition.

Asymmetry in Metallic Zinc and Cadmium

IN the issue of NATURE of February 22, Dr. G. W. Brindley reports on discrepancies in the X-ray scattering factors of zinc and cadmium. The observed values do not lie on a smooth curve. Of the two possible interpretations of this phenomenon, namely (*a*) the asymmetry of the atom or (*b*) the asymmetry in the lattice vibrations, Dr. Brindley gives preference to the latter, since the deviations are too large to be explained by (*a*)[1].

Nevertheless, I wish to say that the possibility of an appreciable variation from a spherical shape of the zinc and cadmium atoms is not altogether out of the question. This opinion is based on the two following observations:

(1) Nineteen of the twenty-one elements having the close-packed hexagonal structure[2] show a ratio c/a between $1\cdot578_5$ (Os) and $1\cdot64$ (Ni). This implies variations of only $-3\cdot3$ per cent and $+0\cdot43$ per cent respectively from the value $1\cdot633$, which corresponds to the case of close-packed spheres. Cadmium and zinc, however, show values of $1\cdot885_9$ and $1\cdot856_2$ ($1\cdot884_3$ resp. at 415°), these ratios being 15½ per cent higher. This difference seems to be too large to be explained by thermal oscillations, should this be taken as the reason for the deviations in the case of the other metals.

(2) The following calculation seems to be of still greater weight. In pursuance of the hypothesis that cadmium and zinc atoms are rotational ellipsoids[3], the question arises, what would be the shape of the ellipse forming the cross-section, that is, what would be its numerical eccentricity. The answer is given by the following calculation for cadmium (p = major, q = minor axis):

$$\frac{p}{q} = \frac{1}{\sqrt{1-\varepsilon^2}} = \frac{(c/a)_{\text{ellipse}}}{(c/a)_{\text{sphere}}} = \frac{1\cdot885_9}{1\cdot6333},$$

and hence $\varepsilon = 0\cdot5002$; that is, equal to 1/2 as precisely as possible[4]. It is difficult to believe that this is a mere chance, especially in view of the considerations mentioned under (1). (There is no intermediate value between $1\cdot64$ and $1\cdot856_2$).

The foci of this ellipse are situated at the centre of each half of its major axis. It is therefore possible to put a sphere in each half of the rotational ellipsoid, their centres coinciding with the foci and their surfaces touching the vertices and the centre of the ellipsoid. Such a rotational ellipsoid, being a 'quasi double-sphere', can be regarded as a body very nearly related to the sphere as to its degree of symmetry.

K. HERRMANN.

[1] See also the paper by C. Zener, *Phys. Rev.*, 49, 122 (1936).

[2] See M. C. Neuburger, "Gitterkonstanten 1936", *Z. Krist.*, 93, 1 (1936).

[3] This view has been mentioned by various writers: Hull, Ewald, Hume-Rothery. See also Canfield, *Phys. Rev.*, 35, 530 (1930)

[4] For zinc at room-temperature with $1\ 856_2$, one gets $\varepsilon = 0\ 475_5$ and at 415° with $1\cdot884_3$, $\varepsilon = 0\cdot4989$.

THROUGH the kindness of the Editor, I have been allowed to see Prof. Herrmann's letter prior to its publication. I entirely agree that the X-ray results do not exclude the possibility that the *outermost* electrons of the atoms in metallic zinc and cadmium may depart from having spherical symmetry; one would not expect the completed inner electron shells to have appreciable asymmetry. The possibility of the outermost electrons being asymmetrical, however, is not to be regarded as an *alternative* explanation of the experimental results, but as something *additional* to the explanation already given in terms of asymmetrical lattice vibrations. The contributions of the outermost electrons to the scattering factors of zinc and cadmium at all angles for which measurements can be made are so small that one could scarcely hope to measure an asymmetry in their distribution by means of X-rays. On the other hand, any asymmetry in the lattice vibrations will affect the entire atom, and at large scattering angles, measurable effects may be expected if the asymmetry is sufficiently great, and this appears to be so for zinc and cadmium.

With regard to point (1) raised by Prof. Herrmann, it is difficult to see whether this indicates an asymmetry of the atoms or of the lattice vibrations, without going into the matter much more fully. If, however, the unusually high c/a values of zinc and cadmium are associated with strongly asymmetrical lattice vibrations, then one might expect that a 'normal' metal, such as magnesium with $c/a = 1\cdot624$, would not show strongly asymmetrical vibrations. I have recently carried out an X-ray investigation of magnesium similar to the previous experiments on zinc and cadmium, and the results so far obtained suggest that in magnesium the lattice vibrations are very much more nearly isotropic than in zinc and cadmium. These results appear to be consistent with the fact that, whereas in zinc and cadmium the thermal expansion coefficients perpendicular and parallel to the principal axis are very different, in magnesium they are almost the same[1].

With regard to Prof. Herrmann's second point[2], that the eccentricity of the ellipsoidal space occupied by an atom in zinc or cadmium is almost exactly 1/2, and that into this space one can place two spheres in contact with their centres at the foci, it is difficult to see what *physical* significance this *geometrical* result can have; if one regards the atom as occupying alternately the two foci, the situation is equivalent to a larger vibration along the *c*-axis than normal to it.

Finally, it may be mentioned that since my letter appeared in NATURE, the results for zinc have been discussed in the *Philosophical Magazine*[2], and a preliminary account of the cadmium results has appeared in the *Proceedings of the Leeds Philosophical Society*[3].

Oxide Layer on a Polished Surface

I CAN confirm S. Dobinski's results[1] for copper by my own experiments on polished aluminium[2]. I used a different method, namely, observations of changes in the initial solution potential when polished under paraffin, benzene, water. The conclusion I came to in my paper was that wet "polishing resulted in the formation of an oxide film in close contact with the metal and similar to that formed by heating in air". This seems further evidence that many observations on the so-called 'amorphous' layer may really have been observations on the properties of the oxide.

Inhibitive Effect of Vitamin C on Toxin Production by *C. diphtheria*

KING and Menten (1935) have reported that guinea-pigs having a high vitamin C storage are less sensitive to diphtheria toxin than are those having a low vitamin C storage. This observation may be important in relation to the pathogenesis of diphtheria infection. We, therefore, tried to ascertain the effect of vitamin C on toxin production by *C. diphtheria in vitro*.

Experiments have been conducted on the influence of vitamin C in the culture media on the toxicity of culture filtrates of a toxin-producing strain of *C. diphtheria*. A sterile solution of vitamin C was added to the culture medium in concentrations ranging from 0·05 to 0·125 per cent. The flasks containing vitamin as well as corresponding controls were inoculated with *C. diphtheria*, incubated 48 hours at 30° C., and the toxicity of the filtrates tested by intracutaneous injection in guinea pigs.

Vitamin C added to culture media rapidly disappears on incubation at 30° or 37° C. However, if immediately after the vitamin is added the medium is inoculated with *C. diphtheria*, the vitamin disappears more slowly. But most significant is the fact that even small residual amounts of the vitamin (20–40 mgm. per cent) are sufficient to inhibit toxin production.

A series of experiments under a variety of conditions has clearly established the fact that vitamin C added in small amounts to a suitable medium inhibits toxin production. The same strain of *C. diphtheria* produces a potent toxin in the flask without vitamin C, and little or no toxin in the one containing the same medium plus the addition of 0·05 per cent ascorbic acid.

It is suggested that the varying toxic character of a diphtheritic injection may depend as much on the tissue saturation with vitamin C as on the toxigenic properties of the infecting strain. It is also possible that the mildness of diphtheritic infection in subtropical and tropical countries is in some way related to the quantitative differences in the concentration of this vitamin. These questions are being investigated.

Induced Chiasma Formation in Somatic Cells by a Carcinogenic Hydrocarbon

EXPERIMENTS are being done on the effects of methylcholanthrene on mouse fibroblasts cultivated *in vitro*. The tissue is grown by the hanging drop method in a medium containing approximately 0·005 mgm. of the hydrocarbon per c.c. and is subcultivated every 48 hours. After three days' growth, the cultures when fixed in Navashin's fluid and stained with iodine-gentian-violet are found to contain a high percentage of abnormal mitotic figures of various types.

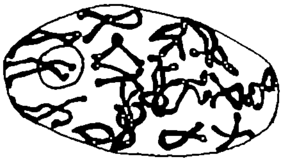

FIG. 1.

Of particular cytological interest is the induction of chromosome pairing and chiasma formation in somatic cells. This condition was observed in several tetraploid cells at various stages from early prophase until anaphase. This disturbance may take the form of a precocity of the prophase in relation to the chromosome splitting, which may also be the underlying mechanism of the induction of chromosome pairing. This suggestion is supported by the abnormal degree of contraction which is observed in the chromosomes both in the cells which show chiasma formation and in the other abnormal cells. The chiasma frequency observed is 1–3 per chromosome as in normal meiosis. A typical prophase cell of this type is shown in the accompanying drawing (Fig. 1) in which some chromosomes have been omitted for clarity.

Isotopes and Molecular Asymmetry

QUITE recently[1], attempts have been made to resolve into their optically active components, molecules of the type $C.H.D.R_1.R_2$, with very slight success, if any at all. In 1922[2], I suggested that if this type of asymmetry associated with isotopes was responsible for very slight rotation or none at all, a molecule of the type $C.x.y.R_1.R_2$. should be investigated, x and y being atoms or groups of similar electronic configuration. In view of the resemblance (which some physicists consider is a real one) between the electronic configuration of the methyl radical and the fluorine atom, the molecule of α-fluor-propionic acid might be a fit subject for investigation. This substance may have no optical activity, if the recent results are correct. I am not aware that asymmetric molecules containing CH_3 and F as dissimilar groups have ever been subjected to optical resolution.

Points from Foregoing Letters

GRAPHS showing the hourly variations in the (square of the) critical penetration frequency (f^2) of radio waves for the C_1 ionizing region of the atmosphere, located at a height of 55 km., are given by Dr. H. Rakshit and J. N. Bhar. Prof. Mitra, commenting on one of their remarks, points out that the critical penetrating frequency cannot be taken as a measure of the density of ionization since it depends upon both ionization density and upon collisional frequency, which vary independently.

An experiment conducted by Chas. R. Burrows on the propagation of ultra-short radio waves over freshwater shows that a revision of the Sommerfeld–Rolf curves is required in those cases where the dielectric constant is taken into account.

Max G. E. Cosyns has measured specific ionization of cosmic rays in hydrogen, helium and argon by comparing the efficiency of Geiger-Müller counters for different internal pressures. The results are given for argon, helium and hydrogen. The absolute intensity of cosmic radiation at Brussels has been found to be 0·0266 per second per sq. cm.

Forty litres of methane with a single substituted deuterium atom have been made by Drs. W. H. J. Childs and H. A. Jahn, in order to obtain its absorption spectrum in the photographic infra-red. Preliminary results are given and the spectrum compared with that of ordinary methane.

From data obtained by Kox on the amplitude of light variation of three separate wave-lengths in different regions of a pulsating star (δ Cephei), and assuming that Planck's formula for 'black body' radiation holds in such cases, A. E. H. Bleksley concludes that the light variations in cepheid variables is consistent with the view that the radius of their photosphere (layer from which comes most of the light that reaches us directly, that is, without absorption and re-emission) is considerably greater at minimum than at maximum luminosity.

In discussing the osmotic function of the contractile vacuoles of Protozoa, Dr. J. A. Kitching points out that while one might expect the rate of vacuolar output to decrease after the external osmotic pressure has been raised above the original internal osmotic pressure of the organism, one would not necessarily expect the contractile vacuole to stop completely. Changes of body volume, and hence of internal osmotic pressure, must also be taken into account.

According to Dr. P. Meyer, the colloid osmotic pressures of the body fluids of freshwater animals are in the order of phylogenetic development, but 20–35 per cent lower than those exerted by the body fluids of the corresponding marine animals. Regarding the freshwater fauna as a regressive branch of the aquatic fauna in general, this is not necessarily contrary to the hypothesis of a relation between the general organization of an animal and the colloid osmotic pressure of its body fluids.

Dr. H. A. Krebs describes chemical changes which pyruvic acid undergoes in living cells. These reactions are intermediate steps in the biological breakdown of carbohydrates; they shed light on the relations between the metabolism of carbohydrates and of ketone bodies, and on the physiological function of vitamin B_1.

D. J. Bell states that glycogen obtained from the whole tissue of the edible mussel, and also from the liver of fasted rabbits (after oral administration of galactose) consists of 18 glucose units, while the glycogen obtained from the liver of rabbits under normal conditions, or that from fish liver, consists of 12 glucose units. No significant difference in the properties of the two glycogens has been observed.

The action of the phosphatase enzyme of the kidney (which splits phosphoric acid esters) is found by Dr. H. Kalckar to be much more strongly inhibited by phloretin than by its glucoside, phloridzin, a bitter principle in the bark of apple and other trees.

It has been found that the vibrational frequency of a molecule AB is the mean of the frequencies of the molecules A_2 and B_2 when A and B belong to the same Periodic Group and where the frequencies of A and B are not too dissimilar. Dr. H. G. Howell points out that this result follows if the force constant is considered to be the same for molecules within a given group.

Prof. K. Herrmann prefers to ascribe certain discrepancies in the X-ray scattering factors of zinc and of cadmium to the asymmetry of the atoms rather than to lattice vibrations, and gives reasons for his preference. Dr. G. W. Brindley, in reply, maintains his opinion that the lattice vibrations are responsible for the asymmetry and considers that, while the outermost electrons of the zinc and cadmium atoms may depart from spherical symmetry, the inner complete electron shells are not likely to do so.

Research Items

Cultural Associations of Solo Man

DR. P. VAN STEIN CALLENFELS has directed attention (*L'Anthropologie*, 46, 3–4) to the character of certain of the artefacts associated with the skulls of Solo man, when these were found in the alluvial gravels of the River Solo at Ngandong, Java, which apparently are of later date than the gravels of Trinil, from which *Pithecanthropus* was derived. The artefacts were scattered over an adjacent area of about fifty metres. They consisted of worked stones of an indeterminate character, and a number of implements of bone and staghorn (chiefly *Cervus Lydekkeri*) with a quantity of bones, for the most part broken. Their contemporaneity with Ngandong man, it would seem, cannot be questioned. They are now in the Bandoeng Geological Museum of Batavia. A flat harpoon with bilateral barbs would be sufficient alone to justify a comparison with the late Azilian harpoons of Scotland, while certain rare forms of Maglemosian harpoon would also serve for comparison. Even more surprising, however, is the association at Ngandong of these archaic skulls with axes of staghorn, of which analogies can be found only in the Mesolithic. The most ancient reindeer horn axes known have been found in northern Europe and belong to the civilization of Lyngby, the first stage of Childe's Forest Culture. At Ngandong the stem of the horn forms the handle and one of the tines forms the blade of the axe. The Lyngby culture belongs to the pre-Boreal post-glacial, and is a little later than Azilian, say 7000–8000 B.C. While all reserve must be shown in comparing two cultures so far removed from one another as that of Ngandong in Java and the Lyngby culture of northern Europe, in estimating the age of Solo man at Ngandong, the associations of artefacts of similar type in Europe must not be forgotten.

Tibetan Blood Groups

PROF. R. RUGGLES GATES, in studying blood-groups of American Indians, has been led to seek an Asiatic people of similar physiognomy, who might be sufficiently high in the O blood-group to have been ancestral to the Indians. One such people, whose blood-groups are wholly unknown, are the Tibetans. Material was obtained through Capt. David Tennant, I.M.S., stationed at Gyantse, Tibet, and the results of its examination are recorded by Prof. Ruggles Gates in *Man* of July. The results, both unexpected and unusual, are as follows: O, 28, 14·9 per cent; A, 88, 47·1 per cent; B, 26, 13·9 per cent; AB, 45, 24·1 per cent; total, 187. By applying the formula $\sqrt{N} = \sqrt{(A+O)} + \sqrt{(B+O)} - \sqrt{O}$, it is evident that the results do not depart significantly from expectation in a homogeneous or well-mixed population. Of the numerous blood-grouping results listed by Steffan, only one has a higher percentage of AB—a series from South Hungary. Some of the Ainu show 25 per cent AB, while the Japanese usually run about 10–15 per cent and some Russian communities have about 15–20 per cent AB. It is evident that these results, the first to be published from Tibet, show that the Tibetans are at the opposite pole from the Americans. No record from any other race shows such a low percentage of O. Another peculiar feature is that AB is nearly double the frequency of B. The percentage of A appears to be the highest recorded for Central Asiatic peoples, being definitely higher than the Chinese, and much higher than the Hindoos. A higher percentage of A is found only in peripheral peoples, such as the Lapps, Bushmen or Australian aborigines. The Tibetans are then well saturated with the blood-groups, and the result is such as might be expected from a people originally very high in A meeting a people, such as the Chinese, with a high proportion (c. 35 per cent) of B.

Reindeer Grazing

IN relation to the pastoral possibilities of the North-West Territories of Canada, some conclusions drawn by Mr. E. Porsild, who has spent several years in charge of experimental herds of reindeer, are contained in an article in the *Geographical Journal* of July. Apart from lake areas and rocky ground that exclude large areas, the ubiquity of insect pests, notably the mosquito, seems to be the limiting factor. Except in the arctic archipelago and along the sea-coast of the mainland, flies and mosquitoes occur throughout the North-West Territories in such enormous numbers during the short summer that "neither the reindeer nor the hardiest of herders can endure their movements". The only escape from these pests is to move the herds to the sea-coast in June and July. There are no hills of sufficient height to be clear of mosquitoes. However, all the Canadian Eskimo tribes without exception live on the coast, and are thus potential reindeer herders. Mr. Porsild considers that among the areas suitable for reindeer grazing, the best is on the west coast of Hudson Bay. An area east of the Mackenzie delta will support great herds, and is now in use. So far, the introduced Alaskan reindeer seem to be doing well.

German Copepods

DR. OTTO PESTA has completed his account of the copepods of Germany and adjacent seas ("Die Tierwelt Deutschlands und der angrenzenden Meeresteile nach ihren Merkmalen und nach ihrer Lebensweise". By Prof. Dr. Friedrich Dahl and others. Teil 29. Krebstiere oder Crustacea. 1: Ruderfüsser oder Copepoda (4, Monstrilloida; 5, Notodelphyoida; 6, Caligoida; 7, Lernaeoida). Jena: Gustav Fischer. 6 gold marks). This is a specially interesting and important part of the section dealing with the Copepoda as it contains the parasitic and semi-parasitic forms. Of the Monstrillidæ, which are planktonic in the adult state and the larvæ of which inhabit polychætes (or, exceptionally, a mollusc), there are four species recorded here, and of the Notodelphyoida, which are commensals or true parasites in echinoderms, ascidians or *Cephalodiscus*, there are three species recorded. All the rest belong to the Caligoida and Lernæoida, both groups represented by numerous species. This is a most useful summary, and is well up to the standard of the former parts, the whole being an indispensable reference book for all working in these regions.

Porcine Trypanosomiasis

HOARE has shown by an exhaustive study (*Trans. Roy. Soc. Trop. Medicine and Hygiene*, 29, No. 6; 1936) that *T. simiæ* is the trypanosome responsible for acute trypanosomiasis of the pig—an animal little subject to infection by the pathenogenic trypanosomes of other domestic animals. Contrary to what was originally thought, it is a polymorphic form, which no doubt accounts for the list of aliases under which it has masqueraded. The intermediate host is the tsetse fly, *Glossina morsitans*, and possibly other species, and the reservoir host is the wart-hog. The etiology and epidemiology of the parasite are discussed.

Varietal Difference in the Potato

THE text of a lecture on "Recent Developments in Connection with the Potato", recently delivered by Dr. T. P. McIntosh before the Royal Caledonian Society, appears in the *Gardeners' Chronicle* of June 6, 13, and 20. Much work relating to the place of origin of the potato was reviewed, and some recent work in Russia suggests that the Peru-Bolivian plateau and south Chile were the two original centres. Dr. McIntosh dealt with his own work on the observation of varietal differences in potatoes, and their detection by chemical means. A test with dilute caustic potash causes the petals, or the flesh of the tuber of some varieties, to turn a vivid canary-yellow. Oxidase tests may also be applied to the tuber for the detection of certain varieties, and the variety Golden Wonder gives an electric-blue fluorescence with ultra-violet light, where other kinds appear red-purple. Characters of tuber sprouts may also be used for diagnostic purposes, and some very interesting colour correlations are set forth. Various experiments on potato breeding are described, and modern work on virus diseases, blight, and other subjects, is reviewed.

Spray Covering on Apples

A SHORT paper by Messrs. Kermit Groves and James Marshall (*J. Agric. Res.*, 51, No. 12, 1139–1142, Dec. 1935) directs attention to the fact that spray fluids applied to fruit crops are often deposited very unevenly upon the developing fruits. They show that more than a third of the total wash received by an apple fruit may collect round the depressions at the calyx and stem ends, and recommendations for estimating spray covering are set forth involving a degree of accuracy which, however, scarcely seems justified in a problem of this calibre.

Vapour Pressure of Deuterium Water

IT is known that the vapour pressure of deuterium water is smaller than that of ordinary water and that the difference becomes smaller as the temperature is raised. F. T. Miles and A. W. C. Menzies (*J. Amer. Chem. Soc.*, 58, 1067; 1936) have determined the pressures for deuterium water at temperatures from 20° to 230° C. by a differential tensimetric method. The results could be reproduced only by a five-constant equation: $\log r = -16{\cdot}998671 + 268{\cdot}8426/T + 7{\cdot}4971604 \log T - 9{\cdot}761107 \times 10^{-3} \times T + 4{\cdot}4288 \times 10^{-6} \times T^2$, where $r = p_{D_2O}/p_{H_2O}$. The normal boiling point of D_2O is calculated as 101·40° ± 0·016°. The temperature at which the vapour pressure of the two varieties of water is identical is calculated as 224·3°, which may be within 0·5° of the truth. Values for the excess of the latent heat of evaporation of D_2O over that for H_2O are calculated. They vary from 300 gm.cal. per mol. at 40° C. to 115 at 220° C. The value at 70° agrees with that found by Lewis and Macdonald for measurements between 20° and 90°.

Exchange Reactions with Isotopes

E. OGAWA (*Bull. Chem. Soc. Japan*, 11, 367, 425, 428; 1936) has described some experiments on the interchange of hydrogen and deuterium in urea, glutamic acid and asparagine and also in carbohydrates, and on the isotopic separation of oxygen, chlorine, bromine and nitrogen by chemical methods. In a further communication to the Editor, he claims to have achieved a separation of nitrogen isotopes by the following method. One kgm. of ammonium chloride (Sample *A*) in 3 litres of water was converted into ammonia (assumed to be NH_3OH_2) by the weighed amount of caustic soda. The ammonia was distilled off and the ammonium chloride was decreased to 47·5 gm. (Sample *B*). This was again decreased to 1·34 gm. (Sample *C*). By interaction with silver nitrate the atomic weights of nitrogen in the samples were determined as 14·002 (*A*), 14·023 (*B*) and 14·105 (*C*). Samples *B* and *C* would then contain 1·61 and 10·5 per cent, respectively, of N^{15} and the separation coefficients would be 5·0 and 3·1. The method depends on a theory of the author according to which the element is richer in heavier isotope when it is in the more positively polarized state. The interchange reaction is $N^{14}H_4{}^{+}Cl^{-} + N^{15}H_3OH_2 = N^{15}H_4{}^{+}Cl^{-} + N^{14}H_3OH_2$.

Plaster of Paris

IT has generally been assumed that plaster of Paris is the hemihydrate of calcium sulphate, $CaSO_4, \frac{1}{2}H_2O$, which on setting takes up water to form gypsum, $CaSO_4, 2H_2O$. Some recent investigations on various lines have been held to show that the water in gypsum is lost on dehydration without any intermediate formation of a lower hydrate, and thus it necessarily follows that plaster of Paris is not a definite hydrate but contains water bound in the state found in zeolites. H. B. Weiser, W. O. Milligan and W. C. Ekholm (*J. Amer. Chem. Soc.*, 58, 1261; 1936) have now published results of X-ray diffraction studies which seem to show that the hemihydrate and dehydrated hemihydrate have not identical structures, as has been asserted. The X-radiograms of the two substances are similar, showing that the structures are similar, but the existence of definite characteristic differences between the two patterns indicates that the water molecules in the hemihydrate occupy fixed positions in the lattice. The results support the view that the hemihydrate is a definite chemical individual, and that the process of dehydration is not zeolitic in character. The isobaric dehydration curves of gypsum also show a very definite break at the composition of the hemihydrate, although both this and anhydrous calcium sulphate adsorb water. The failure of some previous investigators to notice the difference in the X-ray patterns may be due to the use of too small cameras, molybdenum radiation, and failure to use a reference material for standardizing the films. There can be no doubt, the present authors state, that significant differences exist between the X-radiograms of the hemihydrate and its dehydration product when use is made of a relatively large camera, copper radiation, and a standardizing material, and when special care is taken to avoid rehydration of the dehydrated hemihydrate.

Second International Congress for Microbiology

THE week of July 27–August 1 saw more than a thousand microbiologists from all over the world united in conference at University College under the presidency of Dr. J. C. G. Ledingham, director of the Lister Institute. Six years have elapsed since the first Congress in Paris, the original triennial plan having fallen through for reasons which, in view of the world-wide political and economic unrest, may readily be imagined. Much new and important work was therefore ripe for discussion, and the scientific programme had to be divided into no less than eight sections, devoted each to a special subject.

Section 1, under the presidency of Prof. E. Gotschlich, formerly of Heidelberg and now of Ankara, Turkey, dealt with the general biology of micro-organisms. Selective bacteriostasis (the inhibitory action of such substances as dyestuffs and the products of their own metabolism on the growth of bacteria and fungi) and the preservation of micro-organisms in suspended animation, so to speak, by drying in the frozen state were two of the subjects most actively discussed. Their importance is both theoretical and practical: the latter subject especially, interesting in itself in its implications as regards resting states in more highly organized living creatures, has become practically valuable, since it has been realized how subject to variation the unicellular microbe is during culture in the laboratory, particularly variation by loss of such original properties as virulence.

Section 2, devoted to the viruses and virus diseases in animals and plants, under the presidency of Prof. Doerr, of Basle, had perhaps the greatest body of observations to consider, nearly all new since 1930. The five days of discussion, on the general characteristics of viruses, on the modes of transmission and paths of infection in virus diseases, on the evidence concerning the agency of viruses in the ætiology of new growths and on the mechanism of immunity in virus infection, with its practical applications, might alone have furnished material for a congress. Besides the plant diseases in which 'virus' was first discovered, the common cold and influenza, foot-and-mouth disease of cattle, psittacosis, hydrophobia, yellow fever and malignant tumours were all considered in the light of their experimental production by filtrates from which all but 'ultra-microscopic' life had been removed. Astonishing progress was reported in measuring particles of living matter possessing such pathogenic properties, particles not much greater in size than the molecules of comparatively simple chemical compounds, in purifying them and in studying their behaviour in the body fluids of infected and immune subjects: it is gratifying to note how much of it lies to the credit of British research work.

As Bordet put it, in his address as past president to the general assembly of the Congress, "il n'est point de problème plus passionnant, puisqu'il comporte l'étude de la vie dans ces mystérieuses profondeurs où les dimensions deviennent tellement petites que parfois l'on se demande si l'on est encore en presence d'êtres vivants et si les phénomènes qu'on observe ne sont pas dûs à des principes chimiques doués de propriétés imprévues." Yet these particles have been rendered visible and, as 'elementary bodies', have been collected in suspensions of which a dilution of a millionth or more may still produce disease, and multiply indefinitely. Whether they can so multiply apart from the living tissue is yet unsettled: it seems rather that their reproduction is inseparable from the living cell and may indeed be actually a derangement of the cell's own life process.

Section 3, on bacteria and fungi in relation to disease in man, animals and plants, under the joint presidency of Dr. E. J. Butler of the Agricultural Research Council and Prof. H. Zinsser of Harvard, seemed almost staid and commonplace after such adventures in the unknown. Its subjects of highest interest, perhaps, were (1) the general one, on the significance of serological and cultural types of the pathogenic bacteria and fungi in relation to epidemic, epizootic and epiphytotic outbreaks of disease, and (2) the special discussion on the pathogenic streptococci which appear to cause more varied and widespread human misery and death than any other bacterial species.

Section 4, on economic bacteriology, under the presidency of Prof. R. E. Buchanan of Iowa, U.S.A., had to be divided into three subsections: (*a*) dairy, (*b*) water, including sewage and industrial fermentations, and (*c*) soil microbiology. Each of these had its own specialists conferring on its particular problems, but joining with the other subsections for discussion of a subject of general interest, the metabolism of yeast.

In Section 5, on medical, veterinary and agricultural zoology, with Prof. E. Brumpt of Paris as its president, the most active discussion was that on typhus fever and the rickettsias, with chemotherapy of protozoal infections as a close second. The author of "Rats, Lice and History", Prof. Zinsser, appropriately opened the discussion on the former. The similarities and differences, clinical and serological, in the great 'typhus group' of fevers have all been defined in quite recent years; the biology of the infecting microbes, the rickettsias, is, moreover, of particular interest in relation to life-cycles in bacteria, a fascinating field scarcely yet open to exploration.

Section 6, on serology and immunochemistry, was to have been presided over by the arch-priest of the doctrine of antigenic specificity, Prof. Landsteiner of the Rockefeller Institute. Unfortunately prevented, he was replaced by Dr. P. Hartley of the National Institute at Hampstead, himself a serologist of distinction. The study of antigenic structure—and especially of the structure of the new synthetic antigens, the subject of a joint discussion with Section 7—as the new tool for investigating the architecture of living matter, took almost the whole week of the section's time, though it found a day for the significance of allergy in disease, both as a general hypothesis in pathology and as an explanation of such special cases as the cotton-dust asthma, recently elucidated by Prausnitz in Manchester.

Section 7, on microbiological chemistry, had, naturally, Sir Arthur Harden as its president, and a particularly long and varied list of contributions, ranging over growth factors in bacterial culture to the influence of substrate on the chemical potentialities of the cell.

Section 8, on specific immunization in the control of human and animal diseases, was presided over by the veteran Prof. W. H. Park of New York. Its programme was the longest of all, since its subject is the immediate practical concern of health officers in every country, all of them anxious to compare notes and to learn new methods in the prophylaxis of disease. Whooping cough, pneumonia, cerebrospinal fever and the streptococcal infections already mentioned were the chief human diseases in which progress was reported in protective and curative immunology, while in veterinary practice the various anærobic infections, especially, had victories to relate since 1930.

So much for the set discussions: perhaps even more valuable, since they dealt with speculations too young and tender for the rough handling of public debate, were the private conversations during the afternoons free from open sessions. How many of these there were, one can judge only from observation of numerous groups of well-known workers with their heads together in eager talk. Such intercourse may well be the most fertile of all the Congress activities.

A full programme of 'scientific visits' had been arranged for the Congress members and most of the well-known institutes for microbiological research in and near London were 'at home' to visitors on at least one day during the week. The Ladies' Committee had, in addition, organized general excursions for sight-seeing round London which proved extremely popular. The Universities of both Oxford and Cambridge invited and entertained with generous hospitality large parties of Congress visitors.

The Congress closed on August 1 with a plenary session at which resolutions for the alteration of the name and statutes of the original International Society for Microbiology were adopted. Future triennial congresses are no longer only one of the activities of a society, in the sense of a body of society members, unlimited in number, but of a new 'Association of Microbiologists', limited in function mainly to congress organization and in number to one delegate from each participating country. Under the new constitution, the United States invited microbiologists to a congress in 1939 to be held in August on the Atlantic seaboard, and this invitation was accepted by the plenary session with acclamation.

Fruit Supplies in 1935

UNDER the above title, the Imperial Economic Committee has issued a comprehensive supplement to its weekly fruit intelligence notes (London: H.M. Stationery Office, June 1936. 2*s.* 6*d.* net). It will surprise most citizens of the United Kingdom to know that only 79 lb. of fruit per head of the population was eaten in 1935, as against an average of 96 lb. in 1934. Imports of raw fruit, however, exceeded those of any previous year, and made a total of 1,480,000 tons. It is gratifying from an Imperial point of view that 53 per cent of this quantity came from Empire countries overseas, and the amount from this source was greater than the total imports from all sources in the years immediately preceding the Great War.

Home supplies show a rather disturbing variation from year to year, though the acreage under fruit crops does not fluctuate greatly. This is shown in the accompanying table, compiled from information on pages 12 and 14 of the volume, and relating to the orchards and small fruit in England and Wales:

Year	Acreage	Yield, in cwt.
1929	313,295	11,098,000
1930	313,188	10,116,000
1931	306,801	5,871,000
1932	306,839	5,896,000
1933	309,553	9,445,000
1934	315,890	16,217,000
1935	321,963	4,387,000

If the yearly amount of home-produced fruit could be made more or less stable, the consumer would have the benefit of an increased, healthy diet of fruit, whilst the home producer and the importer would find a more uniform and workable market. The reason why the average consumption of fruit was 17 lb. more in 1934 than in 1935 seems to be that there was more than 3½ times the quantity from home sources in the former year than in the latter. Imports could not account for the increased consumption, for 27,069,000 cwt. of fruit came into the country in 1934, and only a slightly larger amount, 29,593,000 cwt., in 1935. Damage by frost may possibly explain the extremely low yield of 1935, though it was not wholly responsible for the small quantities produced in 1931 and 1932. It remains a potent factor, however, as a cause of fluctuating yield, and is beginning to receive the scientific study it deserves.* The so-called "biennial habit" of fruiting, where a year of high yield is followed by a lean season, is not obvious in the returns set forth above. Could not the growers and scientific workers of the country turn their attention to this rather obvious gap in the development of scientific distribution and controlled cropping?

"Fruit Supplies" gives very extensive analyses of the imports of fresh fruit, vegetables, flowers and bulbs into the United Kingdom, and reviews the output of various sources of supply. A useful feature is the statistics of imports into other countries, and the survey should be welcomed by all who are interested in watching the development of Empire resources.

The Hammond Organ

By Sir James Barrett, K.B.E., C.B., C.M.G.

A GENEROUS but anonymous donor has just presented a Hammond organ to the University of Melbourne; and as I am interested in music, especially orchestral music, I am glad to testify to the excellent results obtained from it. The instrument itself is about the size of a small harmonium; it has two manuals and a pedal register, and a foot lever for producing variation in volume. When used fully, the volume of tone is very great, but the musical beauty of the instrument lies even more in the solo stops or arrangements. The clarionet stop produces something superior to any clarionet I have heard, and the volume of tone can be altered at pleasure. The oboe and violin equivalents are very satisfactory.

By combining the various overtones it is obvious that any instrument can be imitated and even improved. The only adverse criticism I have heard is that when the instrument is used fortissimo it is apt to produce a somewhat raucous tone, but that is a matter for the organist to rectify. As the instrument costs about £800, it seems unlikely that many expensive pipe organs will be built in future; and I have no doubt that the Hammond organ represents the commencement of a new development in music.

The following account of the mechanism was kindly furnished me by the professor of physics in the University of Western Australia, Dr. A. D. Ross:

"A synchronous motor rotates at constant speed a shaft provided with sixty-one iron disks, each fitted with a series of projections like teeth. The speed of rotation and the number of projections is such that for any disk the number of projections passing a given point per second is equal to the frequency of the note represented by the disk. When a key of the keyboard is depressed, a magnet is brought close up to the circumference of the associated disk. The passage of the projections of the iron disk causes periodic fluctuations in the magnetic field of the magnet, and consequent induced current in a coil wound on the pole piece of the magnet. The electromotive force for this current varies harmonically, so that the current when supplied to a loud speaker gives a sine-wave movement to the speaker diaphragm and therefore a pure tone. (Unfortunately the material of the diaphragm has its own natural harmonics which are introduced to a slight extent into the tone, and this is one of the chief practical defects in the instrument.)

"When the key middle C of the keyboard is depressed, not only is a magnet brought up to the disk corresponding to frequency 256, but other magnets to the disks for 512, 768, 1024, etc. (the overtones). Each gives alternating electromotive forces with the above-mentioned periodicities, and resultant currents. These currents all pass through separate variable resistances, controlled by the draw-stops (each of which can be moved in or out in eight stages) and so one can utilize the series of electromotive forces corresponding to frequencies 256, 768, etc., in any desired degree of intensity. When the electromotive forces, so adjusted, are applied to a circuit, a current flows with fluctuations corresponding to all the effects superposed. This is amplified and transmitted to the loud speakers, which must produce a sound which has the same fluctuations and is the combination tone with the several harmonics present in the arranged proportions.
